The varnish made and used in China and Japan is composed of turpentine, and a curious sort of oil they have. This they mix and boil up to a proper consistence, and this never causes any swelling in the hands or face of the people who use it. The swellings in these parts, which often happen to those who work the lacquered ware, and sometimes to those who only pass by the shops of these people, is from the lack, and not the varnish. This lack is the sap or juice of a tree, which runs slowly out on cutting the lower part of the trunk of the tree, and is received in pots set on purpose under the incisions. The juice as it flows from the tree is of the colour and consistence of cream; and as it comes in contact with the external air, its surface becomes black. As they only use it when black, their method of preparing it is to let it out in the open air, in large flat bowls, in which it looks all surface; but that the whole may be of the same uniform colour, they continually stir it for twenty-four hours together, with a smooth piece of iron. By this means the whole becomes thicker than it was before, and of a fine deep black. When it is in this state they powder some burnt boughs of trees, and mix them thoroughly with it; and then spreading it thin over any board which they intend to japan, it is soon dried in the sun, and is then absolutely harder than the board it is laid on. When this is thoroughly dry they polish it over with a smooth stone and water, till it is as smooth as glass; and then wiping it very dry, they lay on the varnish, made of oil

and turpentine, and boiled to a proper consistence for this kind of work.

If the work is to be of any other colour than black, that colour is to be mixed with the varnish, and then the whole spread on very thin and evenly, for on this laying it depends the principal part of varnishing. When there are to be figures in gold and silver, these must be traced out with a pencil in the varnish over the rest of the work; and when this varnish is almost dry, the leaf-gold or leaf-silver is to be laid on, and polished afterwards with any smooth substance.

The substances which admit of being japanned are almost those of every kind that are dry, and not too flexible, as wood, metals, leather, and paper prepared. Wood and metals require no other preparation, except that of cleaning their surfaces, and rendering them perfectly even. But leather should be loosely strained either on frames or on boards, and paper should be treated in the same manner, and have a previous strong coat of some kind of size; but it is rarely made the subject of japanning, till it is converted into *paper mâché*, or wrought, by other means, into an inflexible form. One principal variation in the manner of japanning is the using or omitting any priming or under-coat on the work to be japanned. In the older practice, such priming was always used; and it is at present retained in the French manner of japanning coaches and snuff-boxes of the *paper mâché*. But in the Birmingham manufacture it has always been rejected. The advantages attending the use of such priming are, that it makes a saving in the quantity of varnish necessary to be used, and that it helps to form, by means of rubbing and water-polishing, an even surface for the varnish. However, when an under-coat of size is used, the japan coats of varnish and colour will be always liable to crack and peel off, and are less durable than those which are formed without such priming. This difference is observable in comparing the wear of the Paris and Birmingham snuff-boxes.

The laying in of the colours in varnish or oil instead of gum-water, is another variation from the method of japanning formerly practised. But if the colours are tempered with the strongest linseed oil and honey, instead of gum-water, and laid on very flat and even, the work will not be much inferior in appearance to that done by the other method, and will last as long as the common old japan work, the best kinds of the true japan excepted. The proper japan grounds are either such as are formed by the varnish and colour, where the whole is to remain of one simple colour; or, by the varnish either coloured, or without colour, on which some painting or other decoration, is afterwards to be laid. The priming, or undercoat, which is sometimes used in japanning, is of the same nature with that called clear-coating, practised by the bookbinders, and consists in laying on and drying in the most even manner a composition of size and whiting. The common size has been generally used; but in nicer works, the flowers or the parchment size, improved by adding a third of linseed oil, will be preferable. The work should be prepared for this priming, by being well smoothed with fine-skin, or the glass-flower; and by being brushed over once or twice with hot size diluted, when it is of the common strength, with two thirds of water. The priming, formed of a fine whole consistence is between that of the common kind and glass, mixed with as much whiting as will give it a sufficient body of colour to hide the surface on which it is laid, should be laid on evenly with a brush. Two coats of this priming will generally be sufficient; but if, upon trial with a fine wet rag, it will not receive a proper water-polish, another coat or more must be given it. And after the last coat but one is dry, the work should be smoothed by rubbing it with the Dutch rubber. When the last coat is dry, the water-polish should be given, by passing over every part of it with a fine rag, a little mottled, till the whole appears perfectly plain and even. The work is then ready to receive the painting or coloured varnish.

When wood or leather is to be japanned, without priming, it may be prepared by laying on two or three coats of coarse varnish, made by dissolving two ounces of seed-lac, and as much resin in one pint of rectified spirit of wine; and then the proper japan-ground must be laid on. As metals never require to be under-coated with whiting, they must generally be treated in the same manner as wood or leather.

For white-japan-grounds. Prepare a white varnish, by working and grinding flake white, or white lead, with a sixth part of its weight of starch, and drying the mixture; then temper it into a consistence fit for spreading with *medium* varnish, or compound it with gum anime; lay this on the body to be japanned, previously prepared with or without the under-coat of whiting; and varnish it

over with five or six coats of the following varnish, formed by dissolving two ounces of the clearst and whitest grains of seed-lac, and three ounces of gum anime, pulverised, in about a quart of spirit of wine, and straining off the clear varnish.

A very good varnish, free from brittleness, may be obtained by dissolving as much gum anime as the oil will take in old nut or poppy-oil, boiled gently when the gum is put into it. The ground of white colour may be laid on in this varnish, and then a coat or two of it may be put over the ground; but it must be well diluted with oil of turpentine when it is used.

Blue-japan-grounds may be formed of bright Prussian blue; or of verditer glazed over with Prussian blue; or of finally. The colour may be best mixed with shell-lac varnish, and brought to a polishing state by five or six coats of varnish of seed-lac. But when a bright blue is required, and a less degree of hardness can be dispensed with, the method before directed, in the case of white grounds, must be pursued.

Red-japan-grounds. For a scarlet ground, vermilion may be used; but this is less beautiful than the crimson produced by glazing it over with carmine or fine lake, or rose-pink. For a very bright crimson, instead of glazing with carmine, the Indian lake, called *flower*, should be used, dissolved in the spirit of which the varnish is compounded. But in this case, instead of glazing with the shell-lac varnish, the upper or polishing coats must only be used, which will render this a cheaper method than the using carmine. If the highest degree of brightness be required, the white varnishes must be used.

Yellow-japan-grounds. For bright yellow grounds, king's yellow, or turpeth mineral should be used, either by themselves or mixed with fine Dutch pink. The effect may be still more heightened by dissolving powdered turmeric root in the spirit of wine, of which the upper or polishing coat is made; which spirit of wine must be strained off from the drying, before the seed-lac be added to it for forming the varnish.

Yellow grounds may likewise be formed of the Dutch pink only.

Green-japan-grounds may be produced by mixing king's yellow and bright Prussian blue; or turpeth mineral and Prussian blue. A cheap, but fouler kind may be had from verdigris with a little of the fore-mentioned yellows, or Dutch pink. But if a very bright green be wanted, the crystals of verdigris, called *distilled* verdigris, should be used, and their effect will be heightened by laying them on a ground of lead-blue. Any of these may be used with good seed-lac varnish, but will be brighter with the white varnish.

Orange-coloured-japan-grounds may be formed of vermilion or red lead with king's yellow, or Dutch pink; or orange lake, or red turpentine will make a lighter orange ground than can be produced by any mixture.

Purple-japan-grounds may be produced by the mixture of lake and Prussian blue; or a fouler kind, by vermilion and Prussian blue.

Black-japan-grounds may be formed, without heat, by either ivory-black, or lamp-black, which may be laid on with the shell-lac varnish; and the upper or polishing coat may be common seed-lac varnish.

For forming the common *black-japan-grounds* on iron or copper by means of heat, the work must be first painted over with drying oil; and when it is moderately dry, put into a stove of such a degree of heat, as will change the oil black, without burning it. The heat should be slowly augmented and continued for a long time, in order to harden the coat of japan. This kind of varnish requires no polish.

Tortoise-shell-japan-grounds. The best is made by means of the following varnish; prepared by boiling together one gallon of good linseed oil and half a pound of umber, till the oil becomes very brown and thick; by straining the mixture through a coarse cloth, and setting it again to boil, till it acquires the consistence of pitch. On the piece of work to be japanned, well-cleaned, let vermilion, tempered with shell-lac varnish, or with drying oil diluted with oil of turpentine, be laid thinly on the places designed to imitate the more transparent parts of the tortoise-shell.

When the vermilion is dry, brush over the whole with the black varnish, tempered to a due consistence with oil of turpentine; and when it is set and firm, put the work into a stove, where it may undergo a very strong heat, and be continued for a considerable time. This method proposed in one of Kunkel's recipes, has been revived in the Birmingham manufacture, where it is pursued in forming the ground of snuff-boxes, dressing-boxes, tea-waters, &c. this ground may be decorated with painting and gilding in the same manner as any other varnished surface.

Japan-work ou, it properly to be painted with colours in varnish. See PAINTING in varnish and VARNISH. The colours are now most frequently tempered in oil, having a fourth part of its weight of gum anime previously dissolved in it. This oil should be well diluted with spirit of turpentine when it is used, that the colours may be laid more evenly and thin, and thus fewer of the polishing coats of varnish will be necessary. When water-colours are laid on grounds of gold, so as to have the effect of embossed work, they are best prepared by means of singals size corrected with honey or sugar-candy. The body of which the embossed work is raised may be formed of a very strong gum-water, thickened to a proper consistence by bole armeniac and whiting, in equal parts, which being laid on in the proper figure, and repaired when dry, may be then painted with the proper colours tempered in the singals size, or in the general way with shell-lac varnish.

The finishing part of *Japaning* consists of laying on and polishing the water coats of varnish. This is in general best done with common *fact-lac* varnish. But where brightness is principally regarded, the fact-lac must give way to the whiter gums. When hardness, tenacity, and brightness are desired, the mixed varnish made of the picked *resinade*, already propounded under *white Japan grounds*, should be adopted. The pieces of work to be varnished should be placed near a fire, and made perfectly dry; the varnish should then be rubbed over them with proper brushes; fill one coat, and when this is dry another should be laid over it; and this operation must be continued at least five or six times. When a sufficient number of coats is thus laid on, the work is fit to be polished, which must be done, in common cases, by rubbing it with a rag dipped in tripol, commonly called rotten-stone, finely powdered; but toward the end of the rubbing, a little oil of any kind should be used with the powder; and when the work appears sufficiently bright and glossy, the oil alone should be used to clear it from the powder, and to give it a brighter lustre. For white grounds, fine purty or whiting should be used instead of the tripol. For gilding of *Japan work*, see *Japaners* OIL, &c. Handmaid to the Art, vol. ii. p. 479, &c.

JAPONIC Gosselin, see CONNECTION.

JAU, in Ornithology, the name of a Brazilian bird, of the woodpecker kind, called also *japuka*. It is wholly of a fine shining black colour, except that it has a large yellow spot on the middle of each wing, and a broad yellow streak near the rump. This bird hangs its nest very nicely from the extreme boughs of trees; and from the scene, these nests, and not knowing to what bird they belonged, has arisen the error of supposing that the parrots hang their nests in this manner. Ray.

JAR, or **JARA**, from the Spanish, *jara* or *jarrs*, which signify the same, an earthen pot or pitcher, with a big belly, and two handles.

JAR is used for a sort of measure, or fixed quantity of divers things. — The *jar* of oil is from about twenty-six gallons; the *jar* of green ginger is about a hundred pounds weight.

JAR or **JAR**, in Chronology, one of the Hebrew months, answering to our April. It was the eighth month of the civil year, and the second of the sacred, and had only twenty-nine days.

JARARA-COXYPTINGA, in Zoology, the name of a species of serpent found in America, not much unlike the common viper, and equally venomous. Its tail is of a paler colour than the rest of the body, and thence it has its name; which, in the language of the natives, expresses this property.

JARARA-EPERA, in Zoology, the name of a species of American serpent, of a brown colour, but variegated by a very beautiful undulated red line, running all along the back like a chain. Ray.

JARARACA, in Zoology, the name of a species of serpent, common in America. It is a very short serpent, seldom exceeding a foot and a half in length. It has some prominent veins on its head, and is of a dusky brownish colour, variegated with red and black spots. It is a very poisonous species. The natives use it for a remedy the root of a plant called *cassa*, and by the Portuguese *herba de cobra*. Ray.

De Lact has described four different species of this serpent.

JARARACULU, in Zoology, the name of an American species of serpent. It is of the viviparous kind, and produces a great number of young, thirteen having been found perfectly formed in the body of a female of this kind; it grows to between two and three feet long, and has like the other poisonous serpents very large and long teeth, which are hid in the gums, and contain a yellow poisonous liquor. These it only exerts at the

time of biting, and its poison is so fatal, that it will destroy a man within four and twenty hours. Ray.

JARDES, or **JARDONS**, in the *Mangee*, are callous and hard swellings in the hinder legs of a horse, seated on the outside of the hough, as the *spavin* is on the inside. *Jardons* lame a horse, unless you give the fire dexterously and betimes.

JARIBOLUS, *Jaribolus*, in *Antiquity*, one of the Palmyrenian gods. This deity, in the *Mangee*, had the same attributes with the god *Lunus*; for *Jari* signifies the mouth over which the moon presides. Meun. Acad. Inscrip. tom. iii. p. 177.

JARBETIER, in the *Mangee*, an obsolete French word, signifying a horse whose houghs are too close together; which is now expressed in French by *craba*, i. e. crooked or hooked.

JARUS, in *Botany*, a name by which some authors have called the *arum*, or *nut-cake*.

JASIDEANS, in the *History of Religion*. See **JARIDES**. **JASINE**, in *Botany*, a name used by the ancients to express a small kind of climbing plant, much resembling that from which they obtained the drug called *jassmine*. They therefore called this sometimes the small *jassmine*, or *jassmine parva*. It climbed upon trees, and had small ivy-like leaves. Pliny has described such a plant as this under the name of *languria*; and it seems very probable that this was only a corruption of the word *jassine*, that author having taken most of his accounts from the Greeks, and having frequently mistaken their names.

JASIONE, in *Botany, rampant with *jasmine* roots, a genus of the *fraxinifolia* monophylla class: the characters of which are, that it has a common ten-leaved calyx; that the corolla is regular and has five petals; and that the fruit is a bilocular capsule. This plant grows naturally on fertile grounds in most parts of England; and is rarely admitted into gardens.*

JASMELEUM, a medicinal oil, called also by the Persians *jassine*: it is made by putting two ounces of the white flowers of violet into a pint of oil of sassafras. It is used to anoint the body after bathing, and is in great esteem among the Persians for its fragrance, though it is a sort of smell which many would rather think offensive.

JASMINE, or **JESAMINE-tree**, *Jasminum*, in *Botany*, a genus of the *dianthia monophylla* class. Its characters are as follow: the flower has a tubulous empalement, which is permanent, cut into five segments at the brim; the flower is of one petal, cut into five segments at the top, which spread open, it has two short flamina, situated within the tube of the petal; in the centre is situated a roundish germ, which afterwards turns to an oval berry, with a soft skin inclosing two seeds, which are flat on those sides which join, and convex on the other. Miller reckons seven species.

The common white *jassmine* grows naturally in Malabar, and in several parts of India; it has, however, been long introduced to our climate, so as to thrive and flower extremely well, but never produces fruit in England. It is propagated by laying down the branches, which will take root in a year, and may then be cut from the old plant, and planted where they are to remain. It may also be propagated by cuttings, which should be planted early in the autumn, and in a severe winter preferred by tan, saw-dust, or peat-haulm, &c. and when they are removed, they should be planted against a wall, pale, or fence, that may serve to support their flexible branches. These plants should be permitted to grow under in summer, otherwise they will not flower; but after they are past, the branches should be pruned and nailed up about the middle or latter end of March, when the frost is past. Miller.

JASMINE, *Arabian*, *myrsinthus*, in *Botany*, a genus of the *dianthia monophylla* class. Its characters are these: the empalement of the flower is cylindrical, of one leaf, cut into eight acute segments; the flower is of the salver-shape, of one leaf, with a cylindrical tube longer than the empalement, cut into eight segments at the top; it hath two small awl-shaped flamina, situated in the bottom of the tube; and one roundish depressed germin, supporting a single style the length of the tube, crowned by a bifid erect stigma; the germin afterward becomes a roundish berry with two cells, each containing a large roundish seed. Miller reckons only two species, natives of India.

JASMINE, *Esford*, *cystrum*, in *Botany*, a genus of the *dianthia monophylla* class. Its characters are these: it hath a short tubular empalement of one leaf, indented at the top into five parts; the flower is funnel-shaped, of one petal, having a long cylindrical tube, which spreads open at the top, and is cut into five equal segments; and it has five slender flamina; the oval cylindrical germin is situated in the empalement, which becomes an oval oblong berry with one cell, inclosing several roundish seeds.

feels. Miller enumerates six species, natives of the West Indies; they cannot therefore be preserved in England without the heat of a stove, especially in winter.

JASMINA, Bayard. See **LAVIUM** and **BOX-THORN**.

JASMINA, Cyp. See **GARDANIA**.

JASMINA, Fendlerow, a name sometimes given to *gambusia*. See **SOLIS-CONVOLULUS**.

JASMINA, Linnaeus. See **LAVIUM**.

JASMINA, Persia, the name by which some call **LILAC**.

JASMINA, Rob. Pinnell, in *Botany*, a genus of the *pentandria monogyna* class. Its characters are these: the flower has a small caliculus, divided into five parts; it hath one funnel-shaped petal, with a long tube, cut into five oblong oval segments at the top, which spread open; and five awl-shaped stamens, situated in the centre of the tube, terminated by filaments which close together; also an oblong hard germ, with scarce any style, crowned by a double acute stigma; the perianth afterward becomes a long, swelling, acute-pointed capsule, with one cell, filled with winged seeds, placed over each other like scales of fish. Miller enumerates five species.

All these sorts are too tender to thrive in the open air of this country in the summer season, therefore should be constantly preserved in the stove, where, in warm weather, they must have a large share of free air, but in cold weather must be kept very warm. The milky juice of these plants is very caustic, and reckoned poisonous. In cutting off any branches of the plants, if the knife be not immediately cleaned, the juice will corrode it, and turn the blade almost black in a little time so as not to be cleared off again; and if dropped on linen, it will cause it to waste in holes like aqua fortis. Miller.

JASMINA, Scand. and persia. See **COMPET-FLOWER**.

JASMINIDES, in Botany. See **BOX-THORN**, **AVI-BON-BERRY**, and **LICHT**.

JASPAHAYES, in the Natural History of the Antients, a name given to a species of agate, variegated with the matter of the jasper, and therefore being properly distinguished by this name. It is found at this time very plentifully both in the East and West Indies, and in many parts of Italy, Germany, and other parts of Europe; and is a very elegant stone. Its colour is always composed of a brown and green, but it is very irregular in the admixture of these. Sometimes it is one equally coloured mass, and is only distinguishable from the green jaspers by its superior hardness and brightness; but it is much more frequently found of a brownish green ground, variegated with irregular concentric circles of a fairer green, and often with some of a beautiful red, or with a brownish green ground, irregularly clouded and spotted with these colours; it often has also an admixture of white and yellow.

Our lapidaries esteem the oriental pieces of this stone very valuable, and work them into many sorts of toys. The German are sofer, and of little value. Hill's Hist. of Fossils, p. 489.

JASPER, (the word is Hebrew, and has neither been changed by the Greeks, Latins, nor us; some Greek versions give it the name of *hyal*; Onkelos calls it *jasher*, in regard of its being spotted like that animal) *jafus*, in *Natural History*, a genus of stones of the scrup-kind, according to the arrangement of Dr. Hill, greatly resembling the finer marbles, or semi-pellucid gems. According to others, it belongs to the genus of the siliceous or flinty stones; differing from *FLINTS* and *CHERTS*, in being opaque, more easily fusible by fire, in having a granulated texture, and in frequently composing large masses or rocks; whereas flints and cherts are generally in form of nodules or lumps.

Jaspers, though commonly reckoned among the precious stones, undoubtedly belong (says Dr. Hill), to the class of fossils above referred to; being only detached opaque masses of various forms and sizes, and composed of a crystalline matter, debased with an earthy admixture. It is in this last ingredient of their composition, that they owe all their variety of colours, and difference of opacity, whence naturalists have subdivided them into no less than seven orders, containing the white, the green, the red, &c. *jaspers*.

Of the white *jaspers*, there is only one known species, the hard, shining, white marbled *jasper*, commonly called the *NEPHRITIC stone*, on account of its supposed virtue in cases of the stone and gravel. It is found in many parts of America, particularly the great river of the Amazons, and worn by the natives as an amulet. As to its medical virtues, they are too ridiculous to deserve a serious refutation; but its other uses merit the attention of lapidaries, since it is capable of being fashioned into cups and vases of a beautiful polish, and great brightness.

Of the green and greenish *jaspers*, we have the following species: 1. The hard, fine green *jasper*. This is found

in many parts of the world, as Egypt, Tartary, China, &c. and worn as an amulet against fluxes, hæmorrhages, &c. 2. The soft dusky-green *jasper*. This stone, which is of much less beauty and value than the foregoing species, is very common in Germany, Italy, France, England, &c. 3. The hard bluish-green *jasper*, with red variegations; this is the *HELIOTROPE* of the ancients, and *STOOD-STONE* of the moderns. It is common in Africa, Egypt, and the East Indies, and is worked into cups, vases, and snuff-boxes. 4. The hard whitish-green *jasper*, which is the nephritic stone of authors. It is found in many parts of America, where the natives fashion it into figures of birds, beasts, fishes, and other forms; and formerly used to wear it hung to their lower lips. A thousand amazing stories are told, by very grave authors, of the nephritic qualities of this stone. 5. The hard yellowish-green *jasper*, celebrated likewise for its nephritic virtues. It is found in several parts of America, as also in Germany, Bohemia, and some other countries of Europe. 6. The bluish-green earthy *jasper*, variegated with grey and black. 7. The hard, crystalline *jasper*, called by authors the *JAPE*, or *JAVIS DRINK*, the divine stone. 8. The dull deep-green *jasper*, called by different authors *NEPHRITIS*, *NEPHRITIS*, and *NEPHRITIS*. 9. The bluish-green, soft, dull *jasper*. This is the *BEROS*, or *BY-COLOURED JASPER*, of the ancients, and makes a very beautiful appearance in cups, vases, and other ornamental things. 10. The dusky-green *jasper*, variegated with white and flesh-colour; this, though a coarser species than the preceding one, is not without its beauty.

Of the red *jaspers*, we know only four species: 1. The hard, variegated, purple *jasper*; this is the *COLOURED JASPER* of authors. It is a very beautiful stone, and capable of a high polish. It is found in the East and West Indies; also in Germany, Bohemia, and Spain, but of a coarser kind. 2. The bright red *jasper*, variegated with white. America and Europe both afford this species; but those from the former are the finest. 3. The dull purple and white *jasper*. This, though of a coarse and irregular structure, is not infrequently manufactured into handles of knives, and other toys, both in England, Italy, and Germany. 4. The hard, dull, arch-coloured *jasper*. It is of an extremely pale whitish red, generally throughout.

The fourth order of *jaspers* contains those of a pale blue, of which we have only one species, the pale blue *jasper*, with purple veins. It is common in Yorkshire and Suffolk shires, and also in many gravel-pits.

The fifth order contains the yellowish *jaspers*, of which there is only one known species, the yellowish, variegated *jasper*. This is the turpentine-coloured *jasper* of the ancients. It is very common in the East Indies; and we have it also in Germany, Bohemia, and other parts of Europe, but inferior to the oriental ones.

The bluish *jaspers* constitute a sixth order, and of these there are only two species: 1. The pale bluish *jasper*, with black veins and clouds; called by the ancients the smoky *jasper*. 2. The bluish marbled *jasper*, variegated with white.

The seventh and last order of *jaspers* contains the black ones, whereof there are only two species: 1. The black marbled *jasper*, variegated with white. 2. The black marbled *jasper*, variegated with yellow. Hill's Hist. Foss. p. 573-574.

In some of these stones, as also in the agates, nature has amused herself, in representing rivers, trees, animals, landscapes, &c. as if they were painted. The *jasper*, found in the Pyrenees, is usually stained with various colours; though there are some that have but one colour, as red, or green; but these are the least valuable; the most beautiful is that bordering on the black, blue, or purple; next to that, the carmineous, which is now most valued, is the green spotted with red.

The curious Becher having a mind to melt a *jasper*, powdered it, and putting it into a crucible, luted the mouth with it, and giving it an intense fire melted it, and found this very remarkable truth, that the colour of the stone, though no more permanent in the fire than that of other gems, yet may be saved after its being raised in vapour as other sublimed substances are; accident, and not any plan of operation, afforded this; but the fact is worth farther consideration.

On unluting the crucible and opening it, the *jasper* was found melted into one lump, nearly as hard as before; but milk-white and semiopaque, resembling in all respects a natural white agate. The cover and the upper parts of the crucible which were unlined, and which could not be touched by the *jasper* in substance, were tinged with the colours that the *jasper* had lost. These had the appearance of the finest *jaspers*, but the colours were superficial

perforated only, not penetrating into the substance of the matter. The ground was green, as in the natural *jasper*, and the variegations red and yellow, and as beautifully disposed as in the stone itself; the colours were to every laid also that they had a fine polish, and might have passed for wrought *jaspers* of the same species with the melted one, it cunningly set, and not suffered to be handled.

Dr. Brown, in his travels through Germany, gives an account of a male of *jasper* dug out of a quarry at Salsburg, and now making a part of the pavement of one of the emperor's courts at his palace at Vienna, which is of the same kind of disease.

From *fusus jasper*, iron may be obtained; when *jaspers* are figured with specks of onyxes, or agates, they are called *trachypetres*.

JASPEMEDE, in *Natural History*, the name of one of the temperamental gems of the *crystal* kind, very well known among the Italian lapidaries, but very seldom seen among us. It is seldom found of any considerable size, and is composed of broad zones of a pure and elegant white, and a very delicate green, much resembling the matter of some of the green *jaspers*. It is found in the East Indies, and in some parts of America. The Italians are very fond of it, and use it as the common *cameo* for cutting heads and other figures on, either in relief or creux.

JASPONYX, in *Natural History*, the name of the purest horn-coloured *onyx* with green zones; an extremely beautiful stone. It is usually found in the shape of a small pebble, composed of a nucleus of a fluted or flamed crystal, of an irregularly angular figure, round which are alternately disposed zones of a fine pure crystalline matter lightly tinged to a horn-colour, and green ones little inferior to the emerald in beauty, being truly composed of the matter of the finest oriental *jasper*, and sometimes between and among these there are fine slender zones of a pure white, which add greatly to the beauty of the stone. It is found in the East Indies and in New Spain; but in neither of those places very frequently. It is greatly esteemed among all the European nations, and not less so; but its scarcity has given occasion to our jewellers very frequently to put off a green veined German agate under its name. Hill's Min. of Vol. p. 192.

JASPERES MINER. See MARBLE.

JATRAPHITES, (*εσπεριον*), of *lapis*, physician, and *αυρη*, *lapis*, in *Antiquity*, in its original signification, was used for an officer in the gymnasia, whose employment was to point the athletes. The *jatrapietes* was also called *alpheis*, both which terms were sometimes also used to denote the masters of the exercise, such as the *gymnastes* and *pastralis*.

JATRAPHITES is also a term used by the *Ancient Writers* in *Medicine*, to denote such physicians as pretended to cure all diseases by external applications. This method of cure was called *jatrapietes*, and was first introduced into practice among the ancients by Prodicus, a native of Selymbria, and disciple of *Asclepiades*.

JATRAPHITIC, *jatrapietarius*, that part of physic which cures by pungents and frictions; and the application of fomentations, plasters, &c.

JATROCHEMIA, a term used by some writers, to express the method of curing diseases by chemical remedies.

JATROPHIA, in *Botany*. See CASSADA.

JAVELIN, a kind of spear, or half-spike, used by the ancients both on horseback and on foot.

It was five feet and a half long; and the steel wherewith it was headed, had three fides, or faces, which all terminated in a point.

JAUMS, among *Carpeters*, denote the door-posts, as also the upright posts at the ends of window-frames.

JAURES, among *Bricklayers*, &c. the upright sides of CHIMNEYS, from the hearth to the mantle-piece.

JAUNDICE, derived from the French *jaunir*, yellowen, of *jaune*, yellow, in *Medicine*, a disease consisting in a infusion of the bile, and a rejection thereof to the surface of the body, whereby the whole exterior habit is discoloured. Dr. Martini is of opinion that the bile returns into the circulation in this disorder by the course of the lymphatics.

Of this there are three kinds; the first, properly called the *jaundice*, or *yellow jaundice*, is owing to the yellow bile, which, in this case, is too exalted, or too abundant in the mass of blood, or arising from an obstruction of the glands of the liver, which prevents the gall's being duly separated from the blood; or finally, to a stoppage of the puris bilialis, or the like matter, whereby the mixture of that fluid with the aliment in the intestines is prevented.

The second, called the *black jaundice*, is owing to the same bile's being mingled with acids.

The third, bordering on green, takes its rise also from a different mixture of bile with an acid. This is usually called the *chloric*, or green sickness; and is a disorder pretty common in young women.

In the *yellow jaundice*, the albugines, or white of the eye, and the skin, are chiefly yellow; and, besides, they are troubled with an itching. In the *black jaundice*, the natural colour is lost, by reason of an arbitrary humour spread underneath the skin; it appears brownish, and almost black of a lead colour.

The *jaundice* when proves a forerunner of the dropsy. A doctor of the faculty of Montpellier calls the *yellow jaundice*, attended with periodical pains, a *shundies* of the liver; and another of the same place calls it, a *quartan ague of the liver*. The acid spirit of sal ammoniac is said to be an excellent remedy against the *jaundice*.

Medical writers distinguish the *jaundice* into idiopathic and symptomatic. The idiopathic *jaundice* is that which arises of itself, and has no dependence on any other disease; the symptomatic is that which arises in the course of fevers and other distempers, in which the gall is affected.

The yellowness of the skin in some infants as soon as born, is by no means to be supposed a *jaundice*, as it is a thing of no consequence, and usually goes off of itself after voiding of the first stools: being commonly occasioned by the meconium not being sufficiently purged out.

JAUNDICE, *Signs of the*. The disease always attacks people with a remarkable latitude, which lasts for some time; and this is more particularly the case when violent passions of the mind have given rise to the disease: this symptom is succeeded by a sense of a stricture and compression at the pit of the stomach; hence arise anxieties and tightness of the precordia, with difficulty of breathing, which is often violent as to distress suffocation; and usually there is a sense of weight and uneasiness in the right hypochondrium. The patient is always calmer while sitting than while lying or waking. There is a slight fever joined with the other symptoms, the patient being hotter than at other times, and usually feeling a slight chilliness or shivering before this. The bowels are sometimes colder, but sometimes more lax than usual, and the stools are always whitish. These symptoms are very soon succeeded by a yellowness beginning in and about the eyes, and by degrees spreading itself over the whole surface of the body. The urine is at a fine yellow colour, tinged the vessels in which it flows; and if only a few drops of it are poured over a linen cloth, they immediately tinge it like the urine. The appetite is always bad; and when any thing is eaten, the uneasy sensation always returns with more violence at the pit of the stomach. The skin is dry, and the patient generally feels a kind of itching or pricking pain over the whole body. There is a heat in the nostrils, a bitter taste in the mouth, loathing of food, sickness at the stomach, vomiting, and flatulency. The sleep is usually troubled, and there is ever a great languor of the mind attending the disease through all its periods. These are the symptoms of the *yellow jaundice*.

The *black jaundice* is distinguished by a more violent and uneasy dejection and languor of the mind, and the colour brought on by the disease is blackish; and this is not only in the eyes and skin of the whole body, but also in the urine and spittle, or at least the last is of a dusky and deep yellow. To these symptoms there is joined in this case a hectic heat, with great restlessness, wasting of the flesh, and a singular and terrible dejection of the strength; and as there is usually a sensation of a pressure and weight in the right side in the *yellow jaundice*, the same sensation is felt in this on the left. Persons of all ages, and of both sexes, are subject to this disease, but particularly such as are of a choleric habit, and the extremes of life, youth and old age, are more frequently subject to it than the middle stage.

Cause of it. The immediate cause of the *jaundice* is an obstruction of the bile, in its passage into the duodenum, by gall stones, spasm, a scirrhus, whereby it stagnates, is absorbed by the blood and mixed with it. The remote or occasional causes are a coarse and thick diet, and an immoderate stomach for food, a sudden obstruction or retention of humours, particularly of the discharges of the menes and hemorrhoidal veins. In these cases this disease is also too often either the forerunner, or the attendant of an *HYPERBILIS*. It is also sometimes brought on by a suppression of intermittent fever, particularly of quartan by stringency, and by violent passions of the mind, especially when they are suppressed. Violent emetics or purges will sometimes also bring on this disease, as will also a sudden draught of cold water when the body is very hot. It may be also occasioned by the bites of poisonous animals, and by the bilious or hystric

hypertrophic colic. A fistula in the liver, or a stone in the gall bladder, are also known to occasion it. There are the causes of the yellow jaundice; but the black usually takes its rise from obstinate and habitual obstructions of the spleen, which is properly the seat of this disease.

Progress. Young people are seldom violently attacked with the jaundice as those advanced in years, and are always more easily cured of it. When this disease comes on with more than ordinary violence, there is reason to suspect a hectic or low fever at the bottom, or sometimes an acute one. And when a jaundice attacks persons on the fourth day of an acute fever, or before that time, and comes on with great violence, there is always danger of the death of the patient. The greater the obstructions of the viscera are from the suppression of intercurrent issues, the greater is the danger that attends the jaundice arising from such obstructions. People who have had the jaundice two or three times fall into a sort of habitual tendency to it on different occasions, and are usually subject afterwards to frequent returns of it. When the jaundice is attended with great difficulty of respiration, astheny, and oppression about the precordia, and with a sort of sthmatic oppression of the breast, a hectic or hectic, and an atrophy, too frequently follow. If at any time the yellow colour of the skin in this disease changes suddenly to white, it is a very fatal prodrome, shewing that there is a furious confusion in the liver. A discharge of blood by the hemorrhoidal veins happening in the time of this disease, is a prodrome of a speedy cure, and ceases yellow-towers which stain the linen, are also a very favourable symptom. A jaundice which happens to persons advanced in years, from the too free use of stimulents before, is a much more difficult one to cure than the common kind, as there is always in this case a considerable decay of the liver. A jaundice not uncommonly arises from a suppurated abscess of the gall bladder, or even in an infectious manner; and when this proves obstinate and difficult of cure, it gives a very bad prodrome of a hectic, and obstruction of the liver. On the whole, a simple jaundice of the common lighter kind is easily cured, and is of no danger; but when this disease is complicated with others, and is obstinate of cure, it usually proves fatal either in itself, or its consequences.

The black jaundice is always more difficult of cure than the yellow, and where it attacks old people, and is of long standing, it generally proves fatal either in itself, or by bringing on hectic and other incurable disorders.

Method of cure. When the disease is recent, the patient should take three or four times a day powder of nitre and tartar vitriolated; and in cases where violent rillions have been the cause of it, the absorbent powder are to be added, as crebo-eyes, and the like. At times three must be given with these, small doses of rhubarb or other gentle purgatives, and decoctions of turmeric, and a little gallium. By these means a recent jaundice is often happily taken off in a very little time, or, as it were, slipped in the very bud. A few grains of diaphoretic antimony may be added to that powder, which is to be taken going to rest; and this will be very efficacious in ridding off the yellowness of the skin. When the disease is going off by these gentle means, some gentle cathartics are to be given twice a day, and after this the purging by rhubarb is to be repeated. If the patient be young, of a full sanguine habit, and complains of pain to the right-side, about the region of the liver, bleeding will be necessary, and a vomit must be administered half a dram of speakeulana in powder, will be a sufficient dose for an adult, which may be worked off with camomile-tea, or lukewarm water. The body must likewise be kept open by taking a sufficient quantity of Camellie-tea, or of the vitæ for the jaundice: the sal diureticus is an excellent attenuant and deobstruent, and may be given from a dram to a dram and a half, three times a day. Fomenting the parts about the region of the stomach and liver, and rubbing them with a warm bath or bath-brain are likewise beneficial, and the patient may derive great benefit from lining up to the breast in a vessel of warm water.

When the disease is more stubborn, a gentle sweat is to be kept up continually, and powder of turmeric to be given at a scruple for a dose, and powders of diaphoretic antimony and the digestive folio, such as tartar vitriolated, are to be given frequently. Vomits may be also repeated, if there be no sign of inflammation. A dram of solub. tartar may be taken every night and morning, in a cup of tea or warm-spirit, and if it does not open the body, the dose may be increased.

Lice, millipedes, &c. have been recommended for the cure of the jaundice; but their employment in the neglect of more valuable medicines, do more harm than good.

and they are seldom persisted in long enough because they are expected to operate as cathartics. Considerable benefit has been received in a very obstinate jaundice from a decoction of hemp-seed. Four ounces of the seed may be boiled in two quarts of ale, and sweetened with coarse sugar. The dose is half a pint every morning which may be continued for eight or nine days. The waters of Bath and Harrogate are very ferruginous in this disease. The diet of a person in this disease should be cool, light, and diluting, consisting chiefly of ripe fruits and mild vegetables. Many have been cured by living almost wholly for some days on raw eggs. The drink should be butter-milk whey sweetened with honey, or decoctions of cool opening vegetables, as marsh-mallow roots, with liquorice, &c. the patient should use as much exercise as he can bear, take long journeys, pursue diverting amusements, and use every means of promoting the circulation and clearing the spirits. In young people, there needs little more to cure the jaundice than the keeping up a gentle perspiration, and a few doses of rhubarb. Vomits, purges, fomentations, and exercise will seldom fail to cure the jaundice, when it is a simple disease; and when complicated with the dropsy, and a scirrhus liver, or other chronic complaints, it is hardly to be cured by any means. In case of a febrile, the extract of hemlock is reckoned the best palliative. And, in general, as the jaundice is a disease very subject to return upon persons who have once had it, gentle evacuations should be used at times to keep it off, and a medicinal drink with rhubarb, figs, and the like, should be taken for some days once in a quarter of a year.

The jaundice is a disease which will not bear any rough methods; strong purges always do harm, and are forced by the late medicines under the disease worse, instead of giving the relief in it which is always had from perspiration brought on by gentler means.

Persons subject to the jaundice ought to use as much exercise as possible, and avoid all fasting and abstinent diets. Jucker Cond. Med. p. 440-445, &c. Buchan's Dom. Med. p. 493, &c. Hoises are subject to this distemper as well as men. The farriers commonly call it the yellow, and divide it, as we do the jaundice, into two kinds, the yellow and the black. The yellow kind is known by the creature's white of his eyes turning to a yellowish colour, and his tongue and ligaments partaking of the same tinge, but in a lesser degree. In the black kind all these parts are tinged with a dusky or blackish colour. The cure is the same among the farriers as by means of an ounce or two of rhubarb dissolved in two quarts of strong beer, and given three or four times a day, and repeating this dose once in two or three days, as long as the distemper continues.

JAUNDICE-BIRD, JAU-DICK, in Ornithology, a name by which several of the old authors have called the GALLINIA, a bird of the turdus kind, very beautifully coloured all over with a gold yellow, but with black wings.

JAUR-RAIA, in Botany, a name given by Plomer to a genus of plants; another species of which he afterwards describes under the name of *fruticosa* species. The others included by Linnaeus under one genus; the characters of which are delivered in his Genera Plantarum, p. 479. under the name *RAURIA*.

JAW, in Anatomy. See MAXILLA.

Jaw, Dislocated. The lower jaw is seldom luxated, because it is held very firmly by strong ligaments and muscles in two angles in the base of the cranium; but when it is by accident forced from thence, whether it be on one side only, or on both; it is in this case thrust directly forward. This accident is sometimes brought on by a blow, or fall, but most frequently it happens from the opening the mouth too wide in yawning. If it be luxated on both sides, the chin will incline downward, and the jaw will be thrust very forward; but if only on one side, the chin will be inclined towards the opposite side; the clasped little head of the jaw not being capable of dislocation otherwise than forward, and inward. When the jaw is out only on one side, the cure is usually not very difficult; but when both heads are dislocated, and not presently referred to their place, it always occasions the worst of symptoms, as pains, inflammations, convulsions, fevers, vomiting, and even death at length; and these symptoms are the more violent, as the adjacent nerves, tendons, and ligaments suffer a greater extension; but if an expert surgeon is applied to in time, all these are prevented by the ends being reduced.

The patient is to be seated on a low stool, so that an assistant may hold his head firm back against his breast; then the surgeon is to thrust his two thumbs as far back into the patient's mouth as he well can, but they are to be first wrapped round in a handkerchief, to prevent them either from slipping, or from being hurt; his other fingers are at the same time to be applied to the jaw, externally,

ternally. When he has thus firmly got hold of the *jaw*, it is to be strongly pressed, first downwards and then backwards, and fully upwards. These different directions of the force are however to be given all in one instant; and by these means the elated heads of the *jaw*, are at once restored into their former cavities; but the surgeon must also be very careful always to snatch his thumbs very swiftly out of the patient's mouth, lest they should be compressed, bruised, or bit by reducing the *jaw*.

If the *jaw* be out on one side only, the method of reducing it must be exactly the same, only that the luxated side must be forced more strongly downward and backward, than the sound one. As to bandages, there is no occasion for them in this case, unless the luxation has remained some time before it was reduced; for in that case, it may not be improper to apply, for several days, the four-headed bandage, with some strengthening spirit; which may be taken off, when the patient intends to eat. Heister's *Surge*, p. 121.

We have a method, by Mr. Monro, of reducing the *jaw* home when luxated; who says, he has more than once found Mr. Petit's method of reducing the luxated *jaw* bones ineffectual, after the muscles have been swelled by unusual attempts at reduction, but that he succeeded by a small instrument; which was to wrap linen so thick round his two thumbs, that he could scarce introduce them between the posterior grinders; then taking hold of the base of the *jaw*, with his fingers, and applying his palms under the chin, he pressed down and pulled forward the posterior part of the *jaw* with his fingers and the points of his thumbs, which is the whole of M. Petit's method; and at the same time he thrust the anterior part of the *jaw* upwards with his palms, so that the *jaw* being made use of as a lever to which the last joint of the thumbs served as a prop, he acquired a considerable force, to which the muscles were obliged to yield, and the cavities were entirely disengaged from the *apophyses*, and brought down; after which they slide backwards with the least assistance, and the reduction is fully made.

When the thumbs have not force enough to make the reduction, Dr. Simpson, professor of medicine at St. Andrew's, made use of a round piece of wood, eight or nine inches long, one end of which is cut into the form of a wedge, to introduce it between the teeth of the luxated side with the thinnest part, as far back as the posterior grinders; when, having the head secured and raising the chin, he pushes the other end of the wood upwards, to depress the back part of the *jaw* with the thin end, by which the force is much greater than the thumbs can exert.

This learned professor thinks the common opinion, that the *jaw* is brought down by the force of the digestive muscles false; not sufficiently founded. Med. Ess. vol. i. art. 11. and vol. iii. art. 13.

Fracture of the Jaw. The lower jaw is not so liable to fracture as the rest of the bones; but when it is broke, whether it be on one side or both, the divided parts do not recede to any distance from one another. For the restoring the bones in a fractured *jaw* to their proper situation, the patient must be immediately rested over against the light, and his head held firm by an assistant. The surgeon is then to introduce the thumb or forefinger of one hand into the mouth, applying the other externally; and by this means he is to press the fragments of the *jaw* on each side, till they have regained their former situation, which may be always known by the regular disposition of the teeth. And if any of the teeth be found loose or slipped out, it may not be improper, if nothing hinders, to restore them afterwards to their proper places; fastening them by a silver wire to such as are next them. After the bones are thus properly reduced, they must be covered first with a plaster, and then a compress dight in spirit of wine, and applied internally; and another compress sewed to a piece of pasteboard of the form of a half *jaw*, is to be laid on externally; these are to be kept on by a four-headed bandage, perforated in the middle to let in the chin. But when the *jaw* is found to be fractured on both sides, it is usual to introduce and apply internally, after the compresses dight in spirit of wine, another made of thin pasteboard; perforated in its middle, and accommodated to the figure of the chin in this manner. Its middle part is perforated, it is to be applied to the chin, and its two extremities towards the ears. But fractures of this part may often be well enough cured without plasters and splints, where we can conveniently apply a proper bandage; for these bones are not easily displaced again, when they are once reduced. The patient must for some days live upon liquids, avoiding chewing and talking; Vol. II. N° 124.

and the fracture is generally well in twenty or thirty days. Heister's *Surge*, p. 119.

Lock'd Jaw is a spasmodic contraction of the lower jaw, commonly produced by some external injury affecting the tendons or ligaments, and belonging to the class of distempers called *SMYCNATHOTONOS*, *OPITHOTONOS* and *TETANUS*. Opium administered in large doses, and for a considerable time, are the only medicines that insure relief in this disorder. The warm bath and milk have also been found of service. See an account of a variety of cases, with the method of treatment in the London Med. Obs. &c. vol. i. art. 1. art. 7. vol. ii. art. 8. art. 34. vol. iii. art. 31. vol. iv. art. 7.

JAY, in Ornithology, is the English name of the *corvus glandarius* of Linnaeus, with the upper feathers of the wings blue, variegated with black and white; the chin is white; and at the angle of the mouth are two large black spots; the forehead is white, streaked with black; the head is covered with very long feathers, which the bird can erect at pleasure into the form of a crest; the whole neck, back, breast, and belly, are of a faint purple dulled with grey; the rump is white; the tail consists of twelve black feathers; the feet are of a pale brown; the claws large and hooked. The *jay* lays five or six eggs, in a nest formed of the fibres of roots of trees placed on straw sticks. The young follow their parents till the spring; in summer these birds are very injurious to gardens, and in autumn and winter feed on acorns. The *jay* is one of the most beautiful of the British birds; it is very docile, and may be taught to imitate the human voice. When it is cutting its fledged young to follow it, the noise it makes is like the mewling of a cat. Pennant. See Vol. III. Birds, N° 24.

IBERIA, in Ancient Geography, the name by which Spain was anciently known, as well as Georgia in Asia.

IBERIS, in Botany. See *Scutellaria Cerevis* and *Dittander*.

IBEX, in Zoology, the name of an animal of the goat kind. It is found in the mountains, and is extremely swift; but carries on its head a pair of large knotted horns, reclining backwards. Bellonius observes that he saw some whose horns were four cubits long: they are bent down upon the back, and are wreathed and knotty, one knot growing every year. The head is small, and the legs very slender, so that this creature, though properly of the goat kind, much resembles a stag: the male has a very long black beard. It is not uncommon in some parts of Germany. It inhabits the highest Alps of the Grisons country, and it is also found in Crete. The chase of this animal is very dangerous: its blood has been much esteemed in pleuritis. The same species springs from this stock.

IBIBOCCA, in Zoology, the name of a species of serpent called by the Portuguese *corona de coral*. It is about two feet in length, and of the thickness of a man's thumb; and tapers off at the tail to a thinness, till at last it ends in a sharp point. Its belly is all over white, and very bright and glossy; and its head is covered with white scales of a cubic figure, and with some black ones towards the edges. Its body is variegated with black, white, and red. It is a very slow mover; but is of a very terrible and poisonous kind. Ray.

IBIGA, in Botany, a name used by some authors for the chamæpitys, or ground-pine.

IBIJARA, in Zoology, the name of an American species of serpent, called also *ibidy*, and by the Portuguese, *cabe cobra verde*, and *corona de las coqueas*. It is of the amphibious kind, and is generally said to have two heads, one at each end; but that is wholly erroneous. The head and tail are of the same shape, and of equal thickness, and the creature will strike equally with either; and, as it is said, its poison is equally contained at both. It is a snake of the smaller kind, being of about a foot long, and as thick as one's finger. It is white in colour, and as shining and glossy as glass; and is very elegantly marked with rings and streaks of a brown or copper colour. Its eyes are small and scarce conspicuous, looking only like dots made by the point of a needle; it lives under ground, and feeds on ants and other small insects. It is often thrown up in digging; and the Portuguese say, it is a creature whose poison is beyond the reach of all the known remedies. Ray.

IBUJU, in Ornithology, the name of a Brazilian bird, of the caprimulgus, or goot-lucker kind. It is a very beautiful little owl, not larger than a swallow. Its head is large, broad, and flat, and its eyes black and very lively; its beak is extremely small, not exceeding the size of the large fang of a spider; but at the top of this, the nostrils are very distinguishable. Its mouth is monstrously large; when thus it is not perceived, but when it is open, it reaches each way to the eyes. Its legs are very short,

Bird, and its tail broad. It is all over of a blackish colour, spotted and variegated with white and yellow. Margrave.

IBIRA, in *Botany*, a name given by some authors to the tree which produces the cubeba, or cubaba of the shops.

IBIRACOA, in *Zoology*, the name of a species of serpent, found in the West-Indies; whose bite is always attended with very terrible effects. It is of a variegated colour, mottled with black, white, and red.

IBIS, in *Ornithology*, the name of an Egyptian bird, approaching to the stork-kind; and by some confounded very erroneously with the hamatopis, or red-legged heron. It is all over of a fine shining black; its beak is long, somewhat hooked, and all over of a fine red, as are also its legs, which are as long as those of the bittern; its neck is as long as that of the common heron. It is said to be peculiar to Egypt, and is there very serviceable in destroying the serpents, locusts, and other devouring insects; and hence it was, that, in early ages, they had divine honours paid them.

It is remarkable with regard to this bird, that although it lives principally about the Nile, yet it never enters the water, nor can it swim. The six of platters is said to have been learned from the ibis, and not from the duck. It generally builds its nest upon palm-trees, to avoid the cane. Ambrosianus relates, that the flesh of the ibis is red, like a salmon; that it is sweet; that its skin is very hard, and smells like wild-fowl.

IBIRIN, in *Zoology*, the name of a very large and dangerous serpent in the Philippine Isles. This animal twines its tail round the trunk of a tree, and strikes its prey, as men, deer, &c. which it entirely devours, and then squarcs itself against the tree, in order to digest what it has eaten.

IBUM. The Rabbits gave this name to the ceremony of a brother's marrying his sister-in-law, the widow of his brother, deceased without children, by virtue of the Mosaic law mentioned in Deut. xxv.

ICADES, the name of an ancient festival, celebrated every month by the Epicurean philosophers, in memory of their master Epicurus.

The day on which it was held, was the twentieth day of the month, or month, which was that wherein Epicurus was born, and hence came the name *icades*, from *icai*, of *icai*, twenty.

They adorned their chambers on this day, and bore his image in state about their houses, making sacrifices, &c.

ICE, a brittle transparent body, formed of some fluid, frozen or fixed by cold. See FREEZING and FROST.

The specific gravity of ice to water, is as eight to nine; hence, being lighter than water, it floats upon it. The specific gravity of ice was tried by Dr. Irving, in Philp's voyage to the north pole; who found, that when a piece of the most dense ice which he could meet with, was inserted in snow-water, the thermometer 34°, fourteen fifteenths part sunk under the surface of the water; in brandy which is barely floated by, in rectified spirits of wine, it fell to the bottom at once and dissolved immediately. This rarefaction of ice is owing to the air-bubbles produced in ice while freezing; these, being considerably large in proportion to the water frozen, render the ice much specifically lighter. It is well known, that a considerable quantity of air is lodged in the interstices of water, though it has not there any elastic property, on account of the diffusion of its particles; but these particles coming closer together, and uniting as the water freezes, light, expansive, and elastic air-bubbles are thus generated, and increase in bulk as the cold grows stronger; whence of course the ice grows lighter, and these air-bubbles acquiring an elastic force burst to pieces any vessel in which the water is closely contained. But snow-water, or any water long boiled over the fire, affords an ice more solid than ordinary, and with fewer bubbles. Pure water long kept in vacuum frozen afterwards there, freezes much sooner, on being exposed to the same degree of cold, than water unpurged of its air and set in the open atmosphere. And the ice made of water thus divested of its air, is much harder, more solid and transparent, and more ponderous than common ice. See FREEZING and FREEZING-MISTERS. Mr. de Mairan, in a dissertation on ice, attributes the increase of the bulk of the water under this form, principally to a different arrangement of its parts: the ice film on water, being composed of filaments which are found to be joined constantly and regularly at an angle of 60°, and which, by this disposition, occupy a greater volume than if they were parallel. He found the augmentation of the volume of water by freezing, and in different trials a table, as this, at 10th; and when the water was previously purged of air, only a 1st part. Besides, ice after its formation continues to expand by cold; a piece of

ice, which was at first only a fourth part specifically lighter than water, on being exposed some days to the frost, became a 12th part lighter; and thus he accounts for the bursting of ice in ponds.

To make the most perfect ice we should take the purest water, and perfectly purge it of its air by the air-pump; then freeze it in the severest frost, by means of Mr. Fahrenheit's contrivance. Thus we obtain an ice of the greatest hardness, density, purity, transparency, and gravity.

It appears by an experiment of Dr. Hooke in 1663, that ice refracts the light less than water; whence he infers, that the lightness of ice, which causes it to swim in water, is not produced merely by the small bubbles which are visible in it, but that it arises from the uniform constitution of general texture of the whole mass. This fact was afterwards confirmed by M. de la Hire. Hooke's Exper. by Desham, p. 26. Acad. Par. 1663. Mem. p. 25.

Ice is known to evaporate as well as water, and, some say, in a greater degree.

In the mountains of Switzerland there are immense masses of ice, which, by the tradition and histories of the country, must have been there many centuries. At certain times there happens cracks in them, and by these cracks the vast thickness of the masses may in some measure be guessed at; some of them being three or four hundred fathoms deep, and yet none of them ever having gone through the whole thickness.

The vast bodies of ice met with in the northern sea near Hudson's Bay, are surpassing some of them being imported a hundred fathoms or more under the surface of the ocean, and a fifth or sixth part above, and three or four miles in circumference. See Phil. Trans. N° 465, Feb. 2.

The floating mountains of ice owe their vast heights and durable nature to a cause not considered by many; that is, to their not being common ice, but the ice of sea-water; many experiments proving, that in acid and spirituous liquors, when the frost has power over them, the watery parts only are affected, and the ice is brittle, while the liquor remains concentrated, and much stronger than before at the bottom, or in the center. It was generally supposed that the saline liquors, and consequently sea-water, were affected by freezing in the same manner; that is, its watery part alone was frozen, and separated from the part so congealed; but Dr. Linnæus proved, that the ice formed of sea-water was not salt, and does contain sea-salt, and finally that the means of this salt contained in it, rendered it heavier than common ice. If a vial of sea-water be put in the air in frosty weather till flakes of ice are formed in it, and then brought into a warm room, these flakes will remain even in that place a long time undissolved; and if they are taken out and exposed at a small distance to the fire, they will not run into water as common ice would, but they will be heavier, evaporate, and there will be left only a little white salt.

Since sea-water, when frozen, thus forms a very durable ice, it appears easy to conceive, that the immense masses of such ice found in the northern sea should continue undissolved through the whole year, and at the return of the freezing season remaining of the same bigness as at first, they must of consequence then become much bigger by the freezing of more ice about them; and thus continuing to lose very little, and that only by accidents, and annually to increase a great deal. It is not wonderful that they become so large. Phil. Trans. N° 167, p. 436. See SEA-WATER.

But there have been different opinions with regard to the origin of those vast piles of ice, resembling whole islands, in the northern regions. Some ascribe them to snow, which, falling in great abundance, in these cold climates and melting in the sea, accumulates gradually, till these huge heaps are at length formed; but the more common opinion is, that this ice is formed from the fresh waters which flow from the neighbouring lands. It is certain that great quantities of floating ice are discharged by the river Obi, and kept in a state of constant agitation near Bartoli has written an Italian treatise expressly on ice and congelation. And the Acta Eruditorum furnish us with an account of a French author on the same subject. See COAGULATION, and COLD, and CRYSTALLIZATION.

Sir Robert Barker has particularly described the process of making ice in the East Indies, where, during his time, he has never seen any natural ice. For this purpose they dig, in a large open plain, three or four pits, about thirty feet square, and two deep each; the bottoms of which they cover about eight inches or a foot thick with fuzee-cane or the stems of the large Indian corn, dried. On this bed are placed in rows a num-

ber of small shallow unglazed earthen pans, formed of a very porous earth; a quarter of an inch thick, and about an inch and a quarter deep; which, at the dusk of the evening, they fill with soft water that had been boiled. In the morning before sun-rise, the ice-makers attend at the pits and collect what was frozen in baskets, which they convey to the place of preservation. This is generally prepared on some high dry situation, by sinking a pit fourteen or fifteen feet deep, lining it first with straw, and then with a coarse kind of blanket. The ice is deposited in this pit and beat down with rammers, till at length its own accumulated cold again freezes it, and forms one solid mass. The mouth of the pit is well secured from the exterior air with straw and blankets, and a thatched roof is thrown over the whole. The quantity of ice formed by the method above described depends on a light atmosphere, and clear serene weather. Phil. Trans. vol. lxx. p. 11. art. 22.

Ice-hays are large bodies of ice filling the valleys between the high mountains in northern latitudes; the face of which towards the sea is nearly perpendicular, and of a very lively light green colour. Some of these are at least three hundred feet high.

Ice, blink of the, is a name given by the pilots to a bright appearance near the horizon occasioned by the ice, and observed before the ice itself is seen.

Ice-cream, method of making. Take a sufficient quantity of cream, and, when it is to be mixed with raspberry, or currant, or pine, a quarter part as much of the juice or jam as of the cream: after beating and straining the mixture through a cloth, put it with a little juice of lemon into the mould, which is a pewter vessel, and varying in size and shape at pleasure; cover the mould, and place it in a pail about two-thirds full of ice, into which two handfuls of salt have been thrown; turn the mould by the hand-held with a quick motion to and fro, in the manner used for milking chocolate, for eight or ten minutes; then let it rest a long, and turn it again for the same time; and having left it to stand half an hour, it is fit to be turned out of the mould, and to be sent to table.

Lemon juice and sugar, and the juices of various kinds of fruits, are spiced without cream, and when cream is used, it should be well mixed.

Ice-house, a repository for ice during the summer months. The aspect of ice-houses should be towards the east or south-east, for the advantage of the morning sun to expel the damp air, as that is more pernicious than warmth; for which reason, trees in the vicinity of an ice-house tend to its disadvantage.

The best soil for an ice-house to be made in is chalk, as it conveys away the waste water without any artificial drain; next to this, loose stony earth, or gravelly soil. Its situation should be on the side of a hill, for the advantage of entering the cell upon a level, as in the drawing, Tab. II. *Architecture*, fig. 23.

To construct an ice-house, first choose a proper place at a convenient distance from the dwelling-house or houses it is to serve: dig a cavity (if for one family, of the dimensions specified in the design) of the figure of an inverted cone, sinking the bottom, convex, to form a reservoir for the waste water till it can run off; if the soil requires it, cut a drain to a considerable distance, or so far as will come out at the side of the hill, or into a well, to make it communicate with the springs, and in that drain form a *first* or *air-trap*, marked *i*, by sinking the drain to much lower in that place as it is high, and bring a partition from the top an inch or more into the water, which will consequently be in the trap; and will keep the well-air tight. Work up a sufficient number of brick piers to receive a cast wheel, to be laid with its convex side upwards to receive the ice; lay hurdles and straw upon the wheel, which will let the melted ice drain through, and serve as a floor. The sides and dome of the cone are to be nine inches thick; the sides to be done in flamed brickwork, i.e. without mortar, and wrought at right angles to the face of the wall: the filling in behind should be with gravel, loose stones, or brickbats, that the water which drains through the sides, may the more easily escape into the well. The doors of the ice-house should be made as close as possible, and bundles of straw placed always before the inner door to keep out the air.

Description of the parts referred to by the letters.

- a The line first dug out.
- b The brick circumference of the cell.
- c The diminution of the cell downwards.
- d The lesser diameter of the cell.
- e The cast wheel, or joints and hurdles.
- f The piers to receive the wheel or floor.
- g The principal receptacle for straw.
- h The inner passage.
- i The first entrance.
- k The outer door.
- l An air-trap.

m The well.

n The profile of the piers.

o The ice filled in.

p The height of the cone.

q The dome worked in two half-brick arches.

r The arched passage.

s The door-ways entered in the walls.

t The floor of the passage.

u An aperture through which the ice may be put into the cell; this must be covered near the crown of the dome, and then filled in with earth.

v The sloping door, against which the straw should be laid.

The ice, when to be put in, should be collected during the frost, broken into small pieces, and rammed down hard in strata of not more than a foot, in order to make it one complete body; the care in putting it in, and well ramming it, tends much to its preservation.

In a season when ice is not to be had in sufficient quantities, snow may be substituted.

The editor is indebted for this description and drawing of an ice-house to the friendly communication of Mr. Blackburn, an ingenious architect.

Ice may be preserved in a dry place under ground, by covering it well with chaff, straw, or reeds. Phil. Trans. N^o 84. p. 140. See SNOU.

Great use is made of chaff in some places of Italy to preserve ice: the ice-house for this purpose need only be a deep hole dug in the ground on the side of a hill, from the bottom of which they can easily carry out a drain, to let out the water which is separated at any time from the ice, that it may not melt and spoil the rest. If the ground is tolerably dry, they do not line the sides with any thing, but leave them naked, and only make a covering of starch over the top of the hole; this pit they fill either with pure snow, or else with ice taken from the purest and clearest water; because they do not use it as we do in England, to set the bottles in, but really mix it with the wine. They first cover the bottom of the hole with chaff, and then lay in the ice, not letting it any where touch the sides, but ramming in a large bed of chaff all the way between; they thus carry on the filling to the top, and then cover the surface with chaff, and in this manner it will keep as long as they please.

When they take any of it out for use, they wrap the lump up in chaff, and it may then be carried to any distant place, without waste or running. Phil. Trans. N^o 8. See ICE.

Ice-plant, a very singular and beautiful plant of the *fusoides* kind, called by Mr. Tournefort, *fusoides Africanae folio plantaginis undulatae minus argentea odoris*, or the African Scodex with a wavy plantain-like leaf, and covered with silver drops. It is also commonly called with its diamond-plant, and the frost-plant, from its leaves and stalks being all over beset with transparent crystal-like drops, as if covered over with small icicles. This is a species of the *fic moryalis*, or MESSERMARYNTHUM. The seeds of this plant are to be sown very early in the spring upon a good hot-bed; when the plants are come up they are to be transplanted into small pots, filled with fresh light sandy earth, and plunged into another hot-bed; as that hot-bed declines in heat they should be moved into a third, and this will bring them forward toward flowering. In July these plants may be exposed by degrees to the open air, and soon after this their flowers will appear. If it is desired to have these plants very large, they should be hooked out of their pots into an old hot-bed of tanners bark, in which their roots will extend every way, and the branches in proportion; so that a single plant will sometimes spread to a yard square, and its leaves and branches grow to a very surprising size. The flowers of this species are of no great beauty, but its ice-like appearance in the midst of summer is so singular, as to make it very universally admired.

ICELE, in *Mythology*, the son of Sleep, according to the fable, and brother of Morpheus, who is said to have the power of changing himself into a variety of forms; *varia imitantia formas summa, dulcis mentis imago*. Ovid. Met. lib. ii. c. 630.

ICH-DIEN, the motto of the arms of the prince of Wales, signifying in High Dutch, *I serve*.

Sir Henry Spelman judges it to be Saxon, *Ich dien*, the Saxon *di*, with a transverse stroke, being the same with *ich*; and signifying, *I serve*, or *am a servant*, as the ministers of the Saxon kings were called *thiers*, or *thanes*. See *CAVALRY of British Princes*.

ICHNEUMON, in *Zoology*, the name of an animal of which there have been a multitude of idle and fabulous things asserted. It is a creature of the *VIVERRA* kind in the Linnæan system with a longer and narrower body than a cat, and something approaching both in shape and colour to the badger. Its nose is black and sharp, like

like that of the ferret. It has no beard or whisker; its nose is prominent; its ears short and round; and its eyes flame-coloured; its colour is a yellowish grey, much like that of some of the monkey class. This is its appearance when in a good humour; but when frightened or provoked, it raises its hairs upright, and shows them variegated at intervals with grey and yellow in distinct portions; its legs are short, and its feet have all five toes; its tail is very long, and thick at the inferior; its teeth and its tongue like those of the cat; and what is very singular is, that in both sexes it has a large aperture situated below the anus, which it dilates and contracts at pleasure. Hence came the old opinion, that both male and female conceived, and brought forth young in this animal. Its fur is from twenty-four to forty-two inches long, from the tip of the nose to the end of the tail. When it sleeps, it brings its head and tail under its belly, appearing like a round ball, with two legs sticking out. It is naturally a very cleanly animal, and is very bold and nimble, and of great courage. It will engage a large dog, and it has a quarrel with a cat, will destroy that creature by three bites on the throat. Its nose is so sharp and narrow, that it can very hardly lay hold of any thing large with its teeth, and can scarce bite a man's clenched fist. It is very expert in seizing its prey; it stands erect on its hinder legs to devour what it is, then throwing itself flat on its belly, crawls very slowly towards it, and when within reach, darts violently upon it. It feeds indifferently on all animals that it can get at. Its common food are the snail, the lizard, the chameleon, such serpents as it can manage, frogs, rats, and mice; it also very fond of birds, and of none so much as the dove and chicken, and will seize itself dead till they come within reach.

It is much valued in Egypt for destroying serpents, which it seizes very skillfully by the throat, and is kept tame in the houses, as the cat with us. The people call it *Phazendrat*, and the peasants frequently bring its young to market. It is a great destroyer of the eggs of crocodiles, which it digs out of the sand, and even kills multitudes of the young of those terrible reptiles; so that it was not without reason that it was ranked by the Egyptians in the class of their deities. *Tal. III. Quadrupeds, N° 24.*

ICHNEUMONIDÆ, the name given by the old writers on insects to the small slender-bodied wasp, which is frequently found about mud walls, and dry banks of earth. It is very different from the fly simply called the *Ichneumon* of which there are numerous species. This is a true wasp, and is mottled with black and yellow, in the manner of the common wasp. See *Vermilimonæ*.

ICHNEUMONIFERA, in the *Linnean System* is a genus of the *Ichneumonæ* class of insects, comprehending no less than seventy-seven species.

The characters of this genus are, that the mouth has jaws without a tongue; the joints of the antennæ are more than thirty; the abdomen is for the most part ovate, and the sting is thrust out of a cylindric bivalve sheath. Some of the species of this genus have a whitish scutellum, and the antennæ are annulated with a whitish belt. Others have a whitish scutellum, with the antennæ wholly black; and others again have the scutellum of the same colour with the thorax, and the antennæ either annulated with a belt, or black and bristly. The species of *Ichneumon* live chiefly in their caterpillar state, in the bodies of other insects, particularly of the caterpillars of moths and butterflies, in which they deposit their eggs. See *CATERPILLARIFERA*, and *Phil. Trans. N° 76*.

ICHNOGRAPHY, in *Perfektive*, the view of any thing cut out by a plane parallel to the horizon, just at the base or bottom of it.

The word is derived from the Greek *ichnos*, *vestigium*, *passus*, and *grapho*, *scribo*, *describo*; as being a description of the footprints or traces of a work.

Ichthyography is the same with what is otherwise called the *plan*, *geometrical plan*, or *ground-plan*, of any thing, and is opposed to *orthography* or *planivation*. See also *Sectiones aræ* and *Stratægraphia*.

ICHNOGRAPHY, in *Architecture*, is a transverse section of a building, exhibiting the circumference of the whole edifice, and of the several rooms and apartments in the given story; together with the thickness of the walls and partitions; the dimensions of the doors, windows, and chimneys; the projections of the columns and piers, with every thing visible in such a section.

The drawing or designing of this is properly the work of the mæcher-architect, or surveyor; it being, indeed, the most difficult of any.

ICHNOGRAPHY, in *Fortification*, denotes the plan or representation of the length and breadth of a fortress; the distinct parts of which are marked out, either on the ground itself, or upon paper.

ICHOGHANS, the grand seignior's pages, leaving in the seraglio.

The word, according to some authors, is composed of the two Turkish words *ich*, or *del*, which signifies *within*, and *ghos*, *page*. In which sense *ichoghan* is a page serving within the palace, or seraglio. Others derive it from the barbarous Greek *ichnos*, or *traces*; which was formed from the Latin *icula*. These two etymologies give nearly the same sense to *ichoghan*, taking notice for *del* *incula*.

These are the children of Christians, and bred up in an authority scarce to be conceived. The sultan prefers them to officers more or less considerable, as they appear more or less capable, and devoted to his service; but it is to be observed, they are incapable of office till forty years of age, unless they have some particular disposition from the grand seignior. They are educated with a great deal of care in the seragios of Persia, Astracan, and Constantinople. They are under the direction of a capl aga, who presides over their exercises, and treats them with great severity. They are divided into four classes, or chambers, where, according to their several talents or inclinations, they are instructed either in the languages, religion, or exercises of the body.

ICHOR, *icaz*, signifying any *humour*, or *humidum*, properly denotes a thin, watery, humour, like *serum*; but is sometimes also used for a thicker kind, flowing from ulcers; called also *sanie*.

ICHTHYOCOLLA, *Ichmura*, formed of *ichthys*, *fish*, and *colla*, *glue*, popularly called *linguist*, or *fisher*, is a solid glutinous substance, prepared from a fish of the *Sturgeon* kind, caught in the rivers of Russia and Hungary. The *Sturgeon* affords the best; but the sounds of all fresh-water fish yield, more or less, fine *linguist*; particularly the smaller sorts, found in prodigious quantities in the Caspian sea, and several hundred miles beyond Astracan, in the Volga, Yaik, Don, and even as far as Siberia. It is also well known, that our lakes and rivers in North America are stocked with immense quantities of fish, said to be of the same species with those in Muscovy, and yielding the finest *linguist*. The production of *linguist* requires no artificial heat, neither is the matter dissolved for this purpose, as it has been generally imagined; for, as the continuity of its fibres would be destroyed by solution, the mass would become brittle in drying, and snap short & slender, which is always the case with glue, but never with *linguist*. The latter, indeed, may be resolved into glue with boiling water, but the brown recomposition would be found impracticable.

Woods, and a *fibrous* texture is one of the distinguishing characteristics of genuine *linguist*, differing more than certain membranes, and *muscles*, &c. derived from their native mucosity, rolled and twisted into different forms, and dried in the open air. The sounds of air-bladders of fresh-water fish, in general, are preferred for this purpose, as being the most transparent, delicate, flexible substances. These constitute the finest sorts of *linguist*; those called *black* and *ordinary* *linguist* are made of the intestines, and probably the peritoneum of the fish. The sounds, which yield the finest *linguist*, consist of parallel fibres, and are easily rent longitudinally; but the ordinary sorts are found composed of double membranes, whole fibres cross each other obliquely, resembling the coats of a bladder. *Linguist* receives its different shapes in the following manner: the parts of which it is composed, particularly the sounds, are taken from the fish while sweet and fresh, lit open, washed from their slimy fordes, divided of every thin membrane which envelops the sound, and then exposed to stiffness a little in the air. In this state they are formed into rolls about the thickness of a finger, and in length according to the intended size of the *linguist*; a thin membrane is generally selected for the outer of the roll, round which the rest are folded alternately, and about half an inch of each extremity of the roll is turned inward. Having thus settled the proper dimensions, the two ends of what is called the *finest* *linguist* are pinned together with a small wooden peg; the middle of the roll is then pressed a little downwards, which gives it the resemblance of a heart, and thus it is laid on boards, or hung up in the air to dry. The sounds, which compose the long *linguist*, are larger than the former; but the operator lengthens this sort at pleasure, by inter-folding the ends of one or more pieces of the sound with each other. The extremities are fastened with a peg like the former; but the middle part of the roll is bent more considerably downwards, and, in order to preserve the shape of the three obtuse angles thus formed, a piece of round stick is fastened in each angle with small wooden pegs, in the same manner as the ends. In this state it is permitted to dry long enough to retain its form, when the pegs and sticks are taken out, and the drying completed. Lastly, the pieces of *linguist* are joined together in rows, by running pack-

thread through the peg-holes, for the convenience of package and exportation.

The membranes of the book fish, being thick and refractory, will not admit the same formation; and, therefore, the pieces, after their sides are folded inwardly, are bent in the centre, in such manner, that the opposite sides resemble the cover of a book, whence its name; a peg, run across the middle, fastens the sides together, and that it is dried like the former. The cake lingula is formed of the bits and fragments of the staple sorts, put into a flat metalline pan, with a very little water, and heated just enough to make the parts cohere like a pan-cake when it is dried: but this is of little value. Lingula is best made in the summer, as frost gives it a disagreeable colour, deprives it of its weight, and impairs its gelatinous principle.

The founts of cod and ling bear a general likeness to those of theurgeon kind of Linnæus, and are used for the same purpose. The Newfoundland and Iceland fishermen spill open the fish as soon as taken, and throw the back-bones, with the innards annexed, in a heap; but previous to purification, the founts are cut out, washed from their lining, and salted for use. In cutting out the founts, the parts between the ribs are left behind, which are much the best; the Iceland fishermen are so sensible of this, that they beat the bones upon a block with a thick stick, till the *scætes*, as they term them, come out easily, and thus preserve the fount entire. If the founts have been cured with salt, that must be dissolved by steeping them in water, before they are prepared for lingula. The fresh fount must then be laid on a block of wood, whose surface is a little elliptical, to the end of which a small hair-brush is nailed, and with a few knife the membranes on each side of the fount must be scraped off. The knife is rubbed upon the brush occasionally, to clear its teeth; the pockets are cut open with scissars, and perfectly cleaned of the mucous matter with a coarse cloth; the founts are afterwards washed a few minutes in lime-water, in order to absorb their oily principle; and lastly, in clear water. They are then laid upon nets to dry in the air; but, if intended to resemble foreign lingula, the founts of cod will only admit of that called book; but those of ling of both shapes. The thicker the founts are, the better the lingula, excepting its colour; but that is immaterial to the brewer, who is its chief consumer. See Mr. Jackson's Account of the Discovery of the Manufacture of Lingula, in Phil. Trans. vol. lxxii. part 1. p. 1, &c.

Ichthyocolla, or lingula, is one of the purest and kindest of the animal glues, of no particular smell or taste. Heaten into threads, it dissolves pretty readily in boiling water or milk, and forms a gelatinous substance, which yields a mild nutriment, and proves useful medicinally in some disorders arising from a diarrhoea and colliquation of the humours. A solution of it in water, curiously spread, whilst hot, upon silk, affords an elegant sticking-plaster for slight injuries of the skin, not easily separable from the part by water, and scarcely inferior to the more compounded one fold under the name of the ladies black sticking-plaster, in which different balsams and resins are joined to the *ichthyocolla*. See *Extern. Astrucii adhaesum*. Lewis's Mat. Med.

Lingula is used in miniature painting, in the same manner as the gum Arabic or Senegal, for rendering water a proper vehicle, by giving it a due viscosity for spreading and binding the pigments of an earthly texture. But the greatest quantities of it are consumed by brewers, wine-coopers, &c. for fixing their liquors.

A fire may be made of lingula, by boiling half an ounce of the beaten lingula in a pint and a half of water, till the whole be dissolved, and then straining the hot fluid through a linen rag. This fire may be reduced by taking half the above quantity, and adding to it an equal measure of hot water.

A very valuable CLARE is to be made of this drug. It is valuable, in that it will keep aloof, and is a very proper form to keep lingula in, for resins for the wine-cooper's use; besides this it serves also very elegantly for the taking off the impressions of medals, coins, &c. See MEDAL.

ICHTHYOCOLLA FISCI, in *Ichthyology*, the name of a large fish, of the *STURGEON* kind, from which, as also from the *Isle Gormaroun*, the drug called lingula or *ichthyocolla* is made. It is a fish of very great size, and is cartilaginous, having no bones nor scales; its head is large and thick, and its mouth stands very forward; the upper jaw has four fleshy apophyses hanging from it; its eyes are small; its flesh is very well tasted, but glutinous; it is of a yellowish colour, and its tail is large and forked. See *DELUCA-fluv.*

ICHTHYOLOGISTS, authors who have written concerning fishes. The authors who have left in treatises on this VOL. II. N° 181.

subject are very numerous; and are ranged by Artedi into their several proper classes, with great care and candour.

The systematical *ichthyologists* are Aristotle, Pliny, Isidore, Albertus Magnus, Gaza, the interpreter of Aristotle, Marichall, Wootton, Bellonius, Rondestius, Salvius, Gesner, Aldrovand, Johnston, Charlinus, Willughby, Ray, Artedi, and Linnæus.

The *ichthyologists* who have written of the fishes only of some particular places, are these. Ovid, of the fishes of the Euxine; Oppian, of those of the Adriatic; Ausonius, of those of the Mæotis; Mangeli, of those of the Pontic lake; Paulus Jovius, of those of the Tyrrhene sea; Bened. Jovius, of those of the lake Larius; Petrus Gilius, of those of the Massitan sea; Figulus, of those of the Mæotis; Salsian, of those of the Tyrrhene sea; Schwankfeldt, of those of Silesia; Schonefeldt, of those of Hamburg; Margrave, of the Brazilian fishes; Keyfel, of those of Amboyna; and Francis Valentine, of those of the same place. Of these authors, Ovid, Ausonius, Oppian, and Bened. Jovius, wrote in verse, the rest in prose.

The *ichthyologists*, who have copied all they have written from the works of other writers, and therefore least deserve the name, are the following. Piny, Elian, Athenæus, Isidore, the author of the *Libri De Natura Rerum*, Albertus Magnus, Jacques Cobs, Marichall, Gesner in great part, Aldrovand in great part, Johnston, Charlinus, and perhaps some others.

In regard to method, some have written of fishes without any method at all; some have treated of them in the alphabetical order of their names, and some have followed a method more or less perfect throughout their works. Those *ichthyologists* who have attended to no method at all, are Ovid, Elian, Athenæus, Ausonius, Hildegard, De Pinguis, Paulus and Bened. Jovius, Figulus, Salsian in his History of the Roman Fishes, and Ruych. Those who have written alphabetically, are Cobs, Marichall, Salsian in his *Tabula Piscatoria*, Gesner, Schonefeldt, Johnston.

Among the authors who have used some sort of method, those come first who have treated of fishes according to the places where they are usually caught. Of these are Oppian, Rondestius, Aldrovand, Johnston, and Charlinus.

Those who have treated of fishes according to the general division of them into cetaceous, spinose, and cartilaginous, are Aristotle, who was author of the method, Wootton, Willughby, Ray; the last two authors have added to this the numbering the rays of the fins on the back, which is one step toward the Artedian method.

The principal and best authors in this study, and who have reformed and amended it, are Aristotle, Bellonius, Rondestius, Salvius, Gesner, Willughby, and Ray. To these are to be added such as have described only new or particular fishes, who have merited greatly of the world by the new lights they have thrown in upon this part of natural history. These are Paulus Jovius, Petrus Gilius, Schonefeldt, Sibbald, Mangeli, Hebenstreit, and our countryman Mark Catfish; all the rest, except Pliny, Athenæus, Aldrovand, and Johnston, are of no use or value. Willughby is allowed by Artedi to be by far the best author on the subject; but the world will now give that character to Artedi himself. Artedi, De Script. Ichthys.

ICHTHYOLOGY, of *ichthys*, fish, and *logos*, discourse or art, the science which treats of fish. The proper objects of this study are aquatic animals, which have fins, and have no feet. The business of *ichthyology* is, first, to distinguish all the parts of fish by their several proper names; then to adapt to each fish its proper general and specific names; and finally to commemorate some of its particular qualities. See *FISH*, and *GENERAL NAME*.

ICHTHYOMANTIA, *Ichthyomantia*, in *Antiquity*, a species of divination by means of the entrails of fishes.

ICHTHYOPHAGI, *Ichthyophagi*, compounded of *ichthys*, fish, and *phagis*, to eat, *fish-eaters*, a name given to a people, or rather to several different people, who lived wholly on fish.

The *Ichthyophagi*, spoken of by Ptolemy, are placed by Sarton in the provinces of Nauquim and Yantong. Agathides calls all the inhabitants between Carmania and Gedrosia, by the name *Ichthyophagi*.

From the accounts given us of the *Ichthyophagi*, by Herodotus, Strabo, Solinus, Plutarch, &c. it appears, indeed, that they had canals, but that they made no use of them, excepting, as they say, to feed their fish. They made their houses of large fish-bones, the ribs of whales serving them for their beams. The jaws of these animals served them for doors, and the mountains wherein they pounded their fish, and baked it in the sun, were nothing else but their vineyards.

CITHYPERIA, in *Natural History*, the name given by Dr. Hill, to the bony palates of fishes, which are frequently found fossilized at great depths in the earth, and usually immersed in the strata of stone; and in this state had been named by Mr. Lhuys, from their resemblance in shape to the pods of lupines, and some of the other leguminous plants, *Aluphyra*.

Many from this name, and this casual resemblance to the pods of plants, have been misled into the believing them fossils of vegetable origin. But they have plainly all of them been the bony coverings of different parts of the mouths of certain fish of the cartilaginous, and perhaps other kinds, whose principal food being shell-fish, their bony parts were necessary to the eating of them. Many of the *cithyperia* are found indeed plainly worn and rounded by use.

They are sometimes found in their fossil state joined to one another, but commonly in single pieces of joints, or in fragments of such. They are of the same substance with the *trilobites*, and their shape depends on the species of fish, in part of the mouth, to which they belonged. But their most usual figure is that of half the shell of the pod of a lupine. Their sizes are various, from the crust of an inch to two inches in length, and an inch in breadth. Their surface is sometimes smooth and polished; sometimes finely fluted or fluted, and sometimes wholly covered with tubercles. They are also found of very different colours; but most frequently either black, or of a dark chestnut colour.

They are found lodged and bedded in the strata of stone, in Germany, Italy, and France, and in the islands of the Archipelago, and in Syria among the spines of the echinoids, but they are no where so frequent as in England, there being with us very few quarries of stone which do not afford more or less of them. See *Tale of Fossils*, Chap. 3. Hill's *Hill of Fossils*, p. 645.

ICHTHYA, *ichthys*, in *Astronomy*, a famous zodiac of the Egyptian deity, mentioned by Eusebius and St. Austin in the first words of every verse of which make up *Isaiah's* *Spoken Word* *Isaiah's* *Spoken Word* *Isaiah's* *Spoken Word*. The initial letters of which compose the word *Ichthys*, *ichthys*.

ICICA, in the *Materia Medica*, a name given by some to the *cuscuta*.

ICICARILIA, in *History*, a name used by some authors for the tree which affords us the *cuscuta*, used in medicine.

ICCOCA, in *Botany*, the name of a genus of plants, described by Plinius; since called by Linnaeus *Chrysoloma*. See *Coccoloma*.

ICON, *icon*, in *Religion*, the image with *IMAGE*.

CONOCLASTS, or *ICONOCLASTS*, formed from *icon*, image, and *clastis*, to break, in *Ecclesiastical History*, breakers of images; a name which the church of Rome gives to all who reject the use of images in religious matters.

In this sense, not only the reformed, but some of the eastern churches, are called *iconoclasts*, and are all esteemed by them heretics, as opposing the worship of the images of God, and the saints, and breaking their figures and representations to churches.

The opposition to images began in Greece under the reign of Bardanes, who was created emperor of the Greeks a little after the commencement of the eighth century, when the worship of them became common. See *IMAGES*. But the tumults occasioned by it were quelled by a revolution, which, in 717, deprived Bardanes of the imperial throne. The dispute, however, broke out with redoubled fury under Leo the Isaurian, who issued out an edict in the year 726, abrogating, as some say, the worship of images, and ordering all the images, except that of Christ's crucifixion, to be removed out of the churches; but, according to others, this edict only prohibited the paying to them any kind of adoration or worship. This edict occasioned a civil war, which broke out in the islands of the Archipelago, and by the suggestions of the priests and monks, ravaged a part of Asia, and afterwards reached Italy. The civil commotions and infurrections in Italy were chiefly promoted by the Roman pontiffs, Gregory I. and II. Leo was excommunicated, and his subjects, in the Italian provinces, violated their allegiance, and rising in arms either massacred or banished all the emperor's deputies and officers. In consequence of these proceedings, Leo assembled a council at Constantinople in 730, which degraded Germanus, the bishop of that city, who was a patron of images; and he ordered all the images to be publicly burnt, and inflicted a variety of severe punishments upon such as were attached to that idolatrous worship. Hence arose two factions; one of which adopted the adoration and worship of images, and on that account called *iconodules* or *iconotatai*; and the other

maintained that such worship was unlawful, and that nothing was more worthy the zeal of Christians than to demolish and destroy those statues and pictures, which were the occasions of the gross idolatry; and hence they were distinguished by the titles of *iconomachi*, from *icon*, image, and *macha*, I contend, and *iconoclasta*. The zeal of Gregory II. in favour of image-worship, was not only imitated, but even surpassed by his successor Gregory III. in consequence of which the Italian provinces were torn from the Greek empire.

Constantine, called Copronymus, from *copron*, filius, and *onymus*, name, because he was said to have defiled the sacred font at his baptism, succeeded his father Leo in 741, and in 754 convened a council at Constantinople, regulated by the Greeks at the seventh oecumenical council, which solemnly condemned the worship and use of images. Those who, notwithstanding this decree of the council, raised commotions in the state, were severely punished; and new laws were enacted, to set bounds to the violence of monastic rage. Leo IV. who was declared emperor in 775, pursued the same measures, and had recourse to the coercive influence of penal laws, in order to extirpate idolatry out of the Christian church. Irene, the wife of Leo, poisoned her husband in 803, assumed the reins of empire during the minority of her son Constantine, and in 786 summoned a council at Nice in Bithynia, known by the name of the second Nicene council, which annulled the laws and decrees against the new idolatry, restored the worship of images and of the cross, and denounced severe punishments against those who maintained that God was the only object of religious adoration. In this council, the Germans, Franks, and Gauls, were of opinion, that images might be lawfully contained in churches; but they considered the worship of them as highly impious and offensive to the Supreme Being. Charlemagne distinguished himself as a mediator in this controversy; he ordered four books concerning images to be composed, refuting the reasons urged by the Nicene bishops to justify the worship of images, which he sent to Adrian, the Roman pontiff, in 790, in order to engage him to withdraw his approbation of the decrees of the last council of Nice. Adrian wrote an answer, and in 794, a council of three hundred bishops, assembled by Charlemagne at Frankfort on the Main, confirmed the opinion contained in the four books, and solemnly condemned the worship of images. In the Greek church, after the banishment of Irene, the controversy concerning images broke out anew, and was carried on by the contending parties, during the half of the ninth century, with various and uncertain success. The emperor Nicephorus appears, upon the whole, to have been an enemy to this idolatrous worship. His successor, Michael Calapates, surnamed Rhinagrus, patronized and encouraged it. But the scene changed on the accession of Leo the Armenian to the empire, who assembled a council at Constantinople in 814, that abolished the decrees of the Nicene council. His successor Michael, surnamed Balbus, disapproved the worship of images, and his son Theophilus treated them with great severity. However, the empress Theodora, after his death, and during the minority of her son, assembled a council at Constantinople in 842, which reinstated the decrees of the second Nicene council, and encouraged image worship by a law. The council held at the same place under Photius, in 879, and reckoned by the Greeks the eighth general council, confirmed and renewed the Nicene decrees. In commemoration of this council, a festival was instituted by the superstitious Greeks, called the Feast of Orthodoxy. The Latins were generally of opinion, that images might be suffered as the means of aiding the memory of the faithful, and of calling to their remembrance the pious exploits and virtuous actions of the persons whom they represented; but they detested all thoughts of paying them the least marks of religious homage or adoration. The council of Paris, assembled in 824, by Lewis the Meek, resolved to allow the use of images in the churches, but severely prohibited rendering them religious worship. Nevertheless, towards the conclusion of this century, the Gallican clergy began to pay a kind of religious homage to the images of saints, and this example was followed by the Germans, and other nations. However, the *iconoclasts* still had their adherents among the Latins; the most eminent of whom was Claudius, bishop of Turin, who, in 823, ordered all images, and even the cross, to be cast out of the churches, and committed to the flames; and he wrote a treatise, in which he declared both against the use and worship of them. He condemned relics, pilgrimages to the Holy Land, and all voyages to the tombs of saints; and to his writings and labours it was owing, that the city of Turin, and the adjacent country, was, for a long time after his death, much less infected with superstition than

the other parts of Europe. The controversy concerning the sanctity of images was again revived by Leo, bishop of Chalcedon, in the eleventh century, on occasion of the emperor Alexius's converting the figures of silver, that adorned the portals of the churches, into money, in order to supply the exigencies of the state. The bishop obstinately maintained, that he had been guilty of sacrilege; and published a treatise, in which he affirmed, that in these images there resided an inherent sanctity, and that the adoration of Christians ought not to be confined to the persons represented by their images, but extended to the images themselves. The emperor assembled a council at Constantinople, which determined, that the images of Christ and of the saints were to be honoured only with a relative worship; and that invocation and worship were to be addressed to the saints only as the servants of Christ, and on account of their relation to him, as their master. Leo, dissatisfied even with these absurd and superstitious decisions, was sent into banishment. In the western church, the worship of images was disapproved and opposed by several considerable parties, as the Petrobrachians, Albigenses, Waldenses, &c. till at length this idolatrous practice was entirely abolished in many parts of the Christian world by the Reformation. Mosheim's Eccl. Hist. vol. ii. p. 128, &c. 238, &c. See IMAGE.

ICONOGRAPHIA, *ἱκονογραφία*, derived from *ἱκων*, image and *γραφία*, I describe, the description of images, or ancient statues of marble and copper; also of busts and semi-busts, pectates, paintings in fresco, mosaic works, and ancient pieces of miniature.

ICONOLATRE, or **ICONOLATRES**, from *ἱκων* and *λατρεία*, I worship, or **ICONOLATRY**, from *ἱκων* and *λατρία*, I serve, those who worship images; a name which the iconoclasts give to those of the Romish communion, on account of their adoring images, and of rendering to them the worship only due to God. See **ICONOCLASTS** and **IMAGE**.

ICONOLOGIA, formed from *ἱκων* and *λογία*, I speak, the interpretation of ancient images, monuments, and emblems.

ICONOMACHI. See **ICONOCLASTS**.

ICOSAHEDRON, in Geometry, a regular body, or solid, terminated by twenty equilateral and equal angles. The *icosahedron* may be considered as consisting of twenty triangular pyramids, whose vertices meet in the centre of a sphere, imagined to circumscribe it; and therefore they all have their heights and bases equal; wherefore the solidity of one of those pyramids, multiplied by 20, the number of bases, gives the solid content of the *icosahedron*.

ICOSANDRIA, in Botany, the twelfth class of plants with hermaphrodite flowers, and a large number of lamina or male parts in each, comprehending five orders.

The word is derived from the Greek *ἱκων*, twenty, and *ανδρ*, male. See Tab. I. of Botany, Class 12. and Tab. IV. Col. 12.

It should therefore strictly signify a flower with twenty laminae, but it is only understood in an indefinite sense, and made to express such plants as have any larger number, commonly twenty, often more, and those growing to the inner side of the cup of the flower, not to the receptacle of the future seeds. See **FERTIFICATION**.

ICTERIC, derived from the Greek *ικτερις*, which signifies the same; and some derive it farther from *ικτερις*, a kind of weasel with yellow eyes, a term in *Physic*, applied to such persons as have the JAUNDICE; which the Latins call *icterus*, *auriga*, or *maris regius*.

Icteric medicines are those remedies prescribed in cases of the jaundice.

ICTERIC docton. See **MADDER**.

ICTERUS lapi, in Natural History, a name given by the ancients to a stone, famous for the cure of the jaundice. Pliny describes four species of this stone. But these descriptions are so short, that we cannot determine from them which of the stones of those known at present, were intended.

ICTIAR, in the Eastern Military Orders, an officer who has gone through all the degrees or posts in his respective body; and has a right to be a member of the divan.

ICTIS, in Zoology, a name originally Greek, by which some authors call the FERRET.

IDEÆ radii, in Botany, a name used by Columba and some other authors for the large narrow-leaved kind of ruscus, or butcher's broom; called by others *hystrix*.

IDEA, *ἰδέα*, the IMAGE or resemblance of a thing, which, though not seen, is conceived by the mind.

The word is Greek; Cicero renders it into Latin by *exemplar*, and *exemplum*; and Plato himself, in some places, by *εἰκασία*. Cicero, in his Topics, also expresses it by *forma* and *species*.

IDEA, in *Physiology*, denotes the immediate object of the

mind about which we are employed, when we perceive or think of any thing; and this definition of Mr. Locke's is much less exceptionable than that of some other logicians, who define an *idea* to be a pattern or copy of a thing in the mind.

Thus, when we look at the sun, we do not see that luminary itself, but its image, or appearance, conveyed to the soul by the organ of sight; and this image we call *idea*.

The origin of *ideas* has been a long time disputed among philosophers. The Peripatetics maintain, that external objects emit species which resemble them all around; and that these species, striking on our senses, are by them transmitted to the understanding; and that, being material and sensible, they are rendered intelligible by the active intellect; and are at length received by the passive. Others are of opinion, that our souls have of themselves the power of producing *ideas* of things we would think upon; and that they are excited to produce them by the impressions which objects make on the body, though these impressions are not images in any respect like the objects that occasioned them. And in this, say they, it is, that man is made after the image of God, and that he partakes of his power; for as God made all things out of nothing, and can reduce them to nothing when he pleases, so man can create as many *ideas* as he pleases, and annihilate them when he has done.

Others maintain, that the mind has no occasion for any thing beside itself to perceive objects; and that, by considering itself, and its own perfection, it is able to discover all things that are without. Others, with Descartes, hold, that our *ideas* were created and born along with us.

Malebranche, and his followers, assert, that God has in himself the *idea* of all the beings he has created; that thus he sees all things, in considering his own perfection, to which they correspond; and that, as he is intimately united to our souls, by his presence, our mind sees and perceives things in him which represent created beings; and that it is thus we come by all our *ideas*. He adds, that, though we see all sensible and material things in God, yet that we have not out sensuous in him. When we perceive any sensible object, in our perception is included both a sensation, and a pure *idea*. The sensation is a modification of the soul, and it is God who causes it in us; but *for the idea joined with the sensation, it is in God; and it is in him that we see it*.

The Cartesians distinguish three kinds of *ideas*. The first, *innate*, such as they say, is that we have of God, as of a being infinitely perfect. The second, *adventitious*, which the mind receives in proportion as bodily objects present themselves to our senses: such is the *idea* of body, of mind, of figure, light, &c. The third, according to these philosophers, are *falsitious*, which are those which the mind forms, by uniting and assembling the *ideas* which it already had; and these are called *complex*. But Mr. Locke seems to have put this matter out of dispute; having made it appear, that all our *ideas* are owing to our senses; and that all innate, created, and falsitious *ideas*, are mere chimeras.

Our mind, he shews, has not absolutely any *ideas* besides those presented to it by the senses, and those which it forms by its own operations on those others which the senses furnish; so that a man, destitute of one of his senses, would never have any *idea* belonging to that sense; and, supposing him destitute of all the senses, he would never have any *idea* at all; external objects having no other way of producing *ideas* in him, but by means of sensation, he would have no *ideas*, not even of reflection; because in wanting all sensation, he wants that which would excite in him the operations of his mind, which are the objects of his reflection.

It is plain, therefore, there is no innate *idea*; no general truth, or first principle, inherent in the soul, created with it; no immediate object of the mind, before it had perceived external objects by means of the senses, and reflected on that perception. Those *ideas* only seem to be innate, because we find we have them as soon as we come to the use of reason; but they are, in effect, what we formed from the *ideas* wherewith the mind was insensibly filled by the senses. Thus, when the mind is employed about sensible objects, it comes by the *ideas* of bitter, sweet, yellow, hard, &c. which we call *sensation*; and, when employed about its own operations, perceiving and reflecting on them, as employed about the *ideas* before got by sensation, we get the *ideas* of perception, thinking, doubting, willing, &c. which we call *innate sensation, or reflection*; and these two, viz. external material things, as the objects of sensation, and the operation of our own minds, as the objects of reflection, are the only originals whence all our *ideas* have their rise. When we have considered these, and their several modes

and combinations, we shall find, that they contain our whole stock of *ideas*, inasmuch that the understanding does not seem to have the least glimmering of any *idea*, that it did not receive from one of those sources.

And thus far the mind appears merely passive, as not having it in its power to choose whether it will have their first beginnings, or materials of knowledge, or not. For the objects of sense will obtrude their *ideas* upon the mind; and the operations of the mind will not let us be without some (however obscure) notions of them.

The origin of our *ideas* and notions is a perplexed question, and not at all cleared up by the labours of metaphysicians. As to *ideas* of sense, some philosophers have pretended, that bodies acting or pressing upon our nerves, or putting the animal spirits in motion, produce sensation; but as the motion communicated to the nerves or spirits has nothing in common either with the thing as body moving, or with the *idea* excited in the mind, and that we do not conceive the least relation between the motion of the nerves or spirits, and the production of an *idea*, so to say that the motion of, or impression upon the nerves or animal spirits is the cause of *ideas*, is explaining nothing at all.

The species emitted by objects, and the formation of *ideas* by the soul itself, are not more clear. As to innate *ideas*, it is true indeed, that the arguments of those who maintain them, have been refuted by Mr. Locke; but when he goes farther, and denies innate *ideas*, his arguments have been thought by some not to be conclusive.

The opinion of Leibnitz concerning the origin of *ideas*, seems to have some affinity with innate *ideas*. He asserts the soul to be simple, and without parts or composition; hence he concludes, that no created thing can act internally upon it, but that all the changes it undergoes depend upon some internal principle.

God has furnished every soul, so as to have different perceptions; some distinct, many confused; and a great number to obscure, as hardly to be perceived. All these *ideas* together represent the universe; understanding by this term every thing that has been, is, or shall be. According to the different relations that each particular soul has with the universe, some of its *ideas* are distinct, and distinctly represent a certain part of the universe. The foundation of this opinion is, that as each part of the universe distinctly represented, has a necessary relation with every thing that exists, with every thing that has been, or shall be, all things being connected, so that the one is the consequence of another; in like manner, the representation of a certain part of the universe has a necessary and inseparable relation to the representation of the whole.

From whence it follows, that all distinct perceptions of the soul being connected with the *ideas* of all other things, these must likewise be in the soul, though obscurely. In this sense Mr. Leibnitz asserted, that the soul is the mirror of the universe. Now all things that happen in the universe, succeed each other according to certain laws. In like manner in the soul, *ideas* become successively distinct according to other laws; which, though they have a relation to the former, are yet consistent with the nature of intelligence.

All human souls have the same *ideas*, taking the *ideas* of each individual collectively. But distinct *ideas* are not the same in each, these depending upon the relation which each soul has to the universe; and this relation is different, according to the station which God has pleased to assign to each. This seems a fair representation of Mr. Leibnitz's system, relating to the origin of *ideas*; upon which we may remark, that the foundation of this system is, that all the parts of the universe have a necessary connection: but to make just conclusions from this proposition, the connection must be such, that things being considered in themselves, no one thing can be supposed, without all others being to necessary a consequence thereof, that the *idea* of another universe in which there should be any thing belonging to our actual universe, must be contradictory.

If such a connection took place, what is supposed concerning obscure *ideas*, would be true in a certain sense; to wit, that it might be said, that a man who has a distinct *idea* of a triangle, has thereby obscure *ideas* of all the properties of this figure, because of the necessary connection between these last *ideas* and the former.

But no such connection between *ideas* succeeding each other in the soul is perceivable. For if passing from a dark place to one that is enlightened, I thereby suddenly acquire the *ideas* of several objects, never before seen, it does not appear that the previous perception of darkness must necessarily lead me to these new *ideas*.

These and other difficulties may be urged against Mr. Leibnitz's system; nor is Malebranche's more fortunate. This philosopher supposes there can be no cause of an

idea, but this *idea* itself in another intelligent being; and from hence he concludes, that we acquire our *ideas* while our soul perceives them in God.

To prove his opinion, he enumerates all the ways in which the origin of *ideas* is explicable, and concludes, after having refuted all others, that his own is the only true one. But his reasoning labours under two defects. First, who can pretend, in a subject so obscure, to enumerate all the possible ways of the soul's acquiring its *ideas*? He did not know Leibnitz's opinion, very different from that of the Cartesian; and other solutions might perhaps be found out. Secondly, the falsity of other opinions is not sufficiently demonstrated; so that, upon the whole, nothing is yet clear about the origin of *ideas*.

The consideration of the memory does not a little increase the difficulties concerning our *ideas*. Many *ideas* not present may be recalled to mind. These *ideas* are certainly somehow delicately related to the soul than those it never did perceive, or those which it cannot recollect. But what is an *idea* in the soul, which the soul does not yet perceive? Yet such there are. If to explain this we recur to the constitution of the brain, new discoveries arise. What memory can spirits separated from bodies have? If no memory, what intelligence? See Gravesande's Introduction to a Philosophy, p. 134.

As to Malebranche's notion, see also Locke's Posthumous Works, where this opinion is particularly examined; and Berkeley's Dialogues, 2d edit. p. 257, 258, &c.

The ingenious Mr. Harris seems to consider all our *ideas* as innate; originally impressed on our minds by the Deity, and only awakened or called forth by the presence of external objects. *Ideas*, he says, are of the essence of mind, and, therefore, having no relation to corporeal things, cannot be produced by them. But this takes for granted a principle which is contrary to all appearance; viz. that the mind is of such a nature as that it can have no possible connection with matter, or be properly affected by it. Whatever be the nature of the thinking principle, it seems agreeable to fact and universal experience to conclude, that it is capable of being affected, either by natural operation, or, in consequence of an established law, by external objects; and that its perceptions correspond to the state of the corporeal system. Besides, Mr. Harris allows that sensible objects have a natural power of awakening *ideas*; and why may they not have a natural power of originally exciting them in the same mind? Mr. Harris farther argues, that his hypothesis is necessary to account for the identity of the *ideas* of different minds, which could not be explained, if they were only generated from sensible objects, which are fluctuating and variable. But it may be replied, that there is an equal identity or diversity in external objects, as there is in our *ideas* of them; and the correspondence between both is so strict, as to afford a sufficient proof, that our *ideas* have this origin, and no other. This ingenious writer supposes also, that the mental origin of our *ideas* is necessary to account for the correspondence subsisting between the *ideas* of the divine mind, and those of ours, and consequently to the communication between him and us. If sensation were the only source of our *ideas*, this argument would have considerable force; but the contrary appears to be the fact, even upon the system of Mr. Locke, and will be more particularly illustrated in the sequel of this article. See *Hermes*, p. 230, 294, &c. 399, &c. and Priestley's Examination of Dr. Reid's Inquiry, &c. p. 134, &c.

Dr. Price, in his Inquiry into the Original of our *Ideas*, has taken occasion to remark, that the system of Mr. Locke, which ascribes all our *ideas* to sensation and reflection, is materially defective; for, if by sensation we understand the effects arising from the impressions made on our minds by external objects, and by reflection the notice which the mind takes of its own operations, it will be impossible to derive some of the most important of our *ideas* from them. This excellent reasoner observes, that the power within us that understands, the INTUITION of the mind, or the faculty in it that discerns truth, that views, compares, and judges of all *ideas* and things, is a spring of new simple *ideas*, or original, primary, and uncompound perceptions of the mind. To this source he refers our *ideas* of the impenetrability and *vis inertia* of matter, substance, duration, space, infinity, necessity, contingency, possibility, impossibility, power, causation, &c. all our abstract *ideas* (see ABSTRACTION) and also our *ideas* of moral right and wrong, and of moral obligation. It is, he says, of the essence of these *ideas* to imply something true or false of an object; and that they by no means denote the manner in which we are affected by it; so that they cannot with any propriety be referred to that part of our constitution, which has been distin-

distinguished by the appellation of sense. Accordingly, our *ideas* may be divided, first, into those implying nothing real without the mind, or nothing real and true, before its own reflection and passion; to which class we may refer the immediate effects of impressions on the body's senses, without supposing any previous *ideas*, as all tastes, smells, colours, &c. and those that arise upon occasion only of other *ideas*, as the effects in us of confounding errors, happiness, the beauties of poetry, painting, &c. Secondly, into those which are images of something distinct from sensation, or which imply real, independent existence and truth; which may be subdivided into such as denote the real properties of external objects, and the actions and passions of the mind; and those which are derived immediately from intelligence. By the notions conveyed to the mind through the organs of the body, or its observation of the necessary accidents and concomitants of certain sensations and impressions, it perceives the figure, extension, motion, and other primary qualities of material substances; by contemplating ideas, it perceives the properties of spiritual substances, volitions, consciousness, memory, &c. To all these *ideas* it is evident that they have real, certain, invariable, archetypes, actually existing, to which they are referred, and to which they are conformable. These *ideas* again become objects to archetypes to the intellectual faculty, from whence arises a new set of *ideas*, which are the perceptions of this faculty, and represent not the mind's own affections, but secondary truths. Antecedently to this, whatever other *ideas* we may be furnished with, nothing is understood, whatever feels or subjects of knowledge may be in the mind, nothing is known. Price's Review, &c. of Moreau, sect. 3, and 2.

The system of Mr. Locke, with regard to the origin of our *ideas*, has been lately attacked with considerable consequence by Dr. Reid and others; and it has been changed in the foundation of universal scepticism. Dr. Reid objects to every system which supposes that the mind receives images of things from without by means of the senses, because sensations bear no resemblance to bodies, or any of their qualities. With regard to extension, figure, motion, &c. he says, if they are not *ideas* of sensation, not like to any sensation, then the ideal system is a hope of wind, and all the labour'd arguments of the sceptical philosophy against a material world, and against the existence of every thing but impressions and *ideas*, proceed upon a false hypothesis. To this objection it has been replied, that *ideas* are only, in a figurative sense, the images of external things; that certain impressions are conveyed to the mind by means of the organs of sense, and their corresponding nerves, between which, and the sensations existing in the mind, there is a real and necessary, though at present an unknown connection; and that the same reasoning would lead him to deny that sounds are produced by bodies striking against one another, because he can perceive no proper resemblance between the cause and the effect.

Dr. Reid farther objects to the notion generally received among philosophers, that the images of external objects are conveyed by the organs of sense to the brain, and there perceived by the mind. But from this objection it might be inferred, that the whole system of our senses, nerves, and brain, is of no real use whatever; because it is impossible to say how they act upon the mind, or the mind upon them.

It is also objected, that Mr. Locke's division of *ideas* into those of sensation, and those of reflection, is contrary to all the rules of logic, because the second member of the division includes the first. For can we, says he, form clear and just notions of our sensations any other way than by reflection? Sensation is an operation of the mind, of which we are conscious, and we get the notion of it by reflecting upon that which we are conscious of. In like manner, doubting and believing are operations of the mind, whereof we are conscious, and we get the notion of them by reflecting upon what we are conscious of. The *ideas* of sensation, therefore, are *ideas* of reflection, as much as the *ideas* of doubting or believing, or any other *idea* whatsoever. But it has been answered, that the author confines the *idea* of sensation with the *idea* of sensation itself, which is without doubt, of the same class with the *idea* of doubting, &c. as Mr. Locke would have allowed. But the *ideas*, belonging to the class of sensation do not require any scientific knowledge of that power, or any reflection upon it. If this were the case, brutes animals, having no proper *ideas* of reflection, could have no *ideas* of sensation; and the case would be the same with the bulk of mankind. In another place, Dr. Reid acknowledges, that human beings may have *ideas* of mere sensation some time before they discover any power of reflection, and that this power may discover itself, and come into exercise afterwards.

Dr. Beattie, Dr. Oswald, and others, have pursued and extended the same kind of reasoning against the principles of Mr. Locke; and alleged, that Berkeley's reasoning against the existence of a material world, and Hume's reasoning against the existence both of soul and body, are deduced from Locke's *Essay*, and the Principles of His Critics. For an account of Berkeley's system, see ABSTRACTION, BODY, and EXTENSION.

In opposition to this system, Dr. Reid and those who have adopted his theory have resorted to certain instinctive principles; alleging, that our perceptions necessarily imply the belief of the present existence of external objects; and that the real, separate, and independent existence of matter is believed, not because it can be proved by argument, but because the constitution of our nature is such, that we must believe it; and that we cannot, in our own minds, separate the belief of external objects from our sensations. However, it has been urged by an ingenious writer, that Mr. Locke's doctrine is not so favourable to Mr. Berkeley's theory as Dr. Reid's; and that a system which ascribes our primary mental operations to mere configuration and feeling, is more favourable to scepticism than that in the room of which it is substituted. According to Mr. Hume's system, all perceptions are either impressions or *ideas*, and it is not possible for us so much as to conceive any thing specifically different from *ideas* and impressions; and since all *ideas* are copied from impressions, we can, therefore, have no *idea* or conception of any thing of which we have not received an impression. No man can have any *idea* of power or energy, because he has never received any impression of it; and for the same reason no man can have any *idea* of self. What we call a mind is nothing but a bundle or collection of different perceptions, which succeed each other with inconceivable rapidity, and are in a perpetual flux and movement. That is properly, says Mr. Hume, no simplicity in the mind at one time, nor identity at different times, whatever natural propensity we may have to imagine that simplicity and identity. They are the successive perceptions only that constitute the mind; so that there is nothing in the universe but impressions and *ideas*; all possible perceptions being comprehended in those two classes. Consequently, this philosophy, excluding body and mind, admits of no existence whatsoever, not even of a percipient being to be the subject of these perceptions. To the same purpose Dr. Reid observes, that, according to Mr. Locke's system, *being* being the only objects of thought, and having no existence but when we are conscious of them, it necessarily follows, that there is no object of our thought which can have a continued and permanent existence. Body and spirit, cause and effect, time and space, to which we were wont to ascribe an existence independent of our thought, are all turned out of existence by this short dilemma. Either these things are *ideas* of sensation or reflection, or they are not: if they are *ideas* of sensation or reflection, they can have no existence but when we are conscious of them; if they are not *ideas* of sensation or reflection, they are words without any meaning. To which we shall only reply, that we have the same reason to believe, that mind exists as that body exists; since it is only by that name that we distinguish the subject of certain powers or properties, of which we are conscious, as perception, memory, will, &c. and we have just the same reason to believe the identity of an *idea* as that of any external body, or that of our own minds.

Those who wish to be further acquainted with the controversy relating to the nature and origin of our *ideas*, must be referred to Hume's Treatise of Human Nature, vol. i. p. 123, &c. 282, &c. 434, &c. Reid's Inquiry into the Human Mind, passim. Beattie's Essay on Truth, part ii. chap. 2. Priestley's Examination of Reid, Beattie, &c. passim. See COMMON SENSE.

For an account of Dr. Hartley's system of the generation of our *ideas*, see ASSOCIATION, VIBRATION, and VIBRATIONS.

The term *idea* has, by Mr. Locke, been extended to every thing we know or have any notion of, any thing about which the mind is employed in thinking. But this extensive use of the term *idea* is thought improper by a very ingenious and acute writer, who observes, that we may be said to have some knowledge or notion of our own minds, of spirits and active beings, whereof in a strict sense we have not *ideas*. In like manner, we know and have a notion of relations between things or *ideas*, which relations are distinct from the *ideas* or things related, inasmuch as the latter may be perceived by us, without our perceiving the former. The same author elsewhere observes, that by mind, spirit, soul, or self, he does not denote any one of his *ideas*, but a thing entirely distinct from them; wherein they exist, or which is the same thing

thing, whereby they are perceived; for the existence of an *idea* consists, as he says, in being perceived. He also observes, the word *thing* or *being*, is the most general name of all, and comprehends under it two kinds entirely distinct and heterogeneous; having nothing common but the name, to wit, *things* and *ideas*. And in another part of his treatise, he expressly shews, there can be no *idea* formed of a soul or spirit. Berkeley's *Princ. of Human Knowledge*, § 2. 27. 35. 147.

Another author has also blamed Mr. Locke for confounding *ideas* and *visions*. He observes, that by *idea*, according to the common, and most usual signification of the word, is meant the image, picture, or representation in the mind of a sensible appearance, or of an object which had before been perceived by sense. To which sensible appearance, therefore the *idea* necessarily refers, for whatever is in it, or upon any account can be ascribed to it, and it refers, is made use of in its stead, for the mind to contemplate or enjoy itself about in thinking, at such time when the object it represents is not immediately perceived, as in the act of *ideas*. Vide p. 102 & 105, of a book, intitled, Two Dissertations concerning *Sense* and the *Imagination*, with an *Essay* on *Consequences*. Lond. 1728. 8vo.

This author further shews, in opposition to Mr. Locke, that the perception of an *idea* is not an act of the understanding. He says, that an *idea*, by Mr. Locke's own account of it, is an object, or something perceived, and about which the mind is employed in thinking. Wherefore if perception (suppose) which is an operation or act of the mind, should itself be considered as an *idea*, (and under this very title Mr. Locke treats of perception) then one *idea* would be the object of another *idea*, and so there would be an *idea* of an *idea*, or an object of an object; and one *idea* would perceive another *idea*, which there is no making any tolerable sense of. And indeed in explaining or declaring the operation of any faculty, to give it the same name and appellation with the object itself about which it is employed, and which there is a necessity of considering, in order to set forth the particular quality and nature of the operation, and the precise manner of its concerning and having to do with the object, seems very inconsistent with such a purpose or design.

This author has been very elaborate in proving and enforcing the distinction between *visions* and *ideas*. In another treatise he observes, that Mr. Locke, in his *Essay* on *Human Understanding*, takes no notice of rational notions, and thereby has not only given a partial and imperfect account of his subject, but made an unjust and unfair representation of it. Vide an *Essay* concerning *Rational Notions*, printed at London, 1723.

That some confusion may have arisen from giving the same name to these heterogeneous things, cannot be questioned. However, Mr. Locke is in this respect no more guilty than Malbranche and the Cartesian, who use the term *idea* in the same extensive sense with him, and from whom indeed he seems to have taken it. But then the Cartesian seem to have been more cautious to distinguish between the *idea* of the imagination, and those of the intellect, understanding or *de seipso* per, as they sometimes express themselves, and have thereby guarded against the inconvenience arising from the too general signification of the term *idea*. See NOTION.

Ideas, according to Mr. Locke, are divided into *sensory* and *reflective*. *Ideas*, include all those which come into the mind by sensation; and though the qualities of bodies that affect our senses, are in the things themselves to mind, and unaided, that there is no separation between them, yet the *ideas* they produce in the mind are simple and un-mixed. Again, some of these *ideas* we acquire purely by means of our sense; as the *idea* of colour, only by the eye; of sounds, by the ear; of heat, by the touch, &c. Other *ideas* we gain by several senses, as of space, extension, figure, rest, motion, &c. for these have their effects, both on the sight and the touch. Others, again, are had from reflection only; such as those of perception and willing. These are other simple *ideas*, again, formed in the mind, both by sensation and reflection, jointly; as those of pleasure, pain, power, existence, unity, succession, &c. And some of these kinds of *ideas* are all, or at least the most considerable, of those simple *ideas* which the mind hath, and out of which is made all its other knowledge.

'Tis better to comprehend the nature of simple *ideas*, it will be convenient to distinguish between them, as they are *ideas* of perceptions in our minds, and as they are modifications of the bodies that cause such perceptions in us, that we may not think, as it is usually done, that they are exactly the images and resemblances of something inherent in the object; for most of those of sensa-

tion are in the mind no more the likeness of any thing existing without us, than the names that stand for them are the likeness of the *ideas*.

But here the qualities of bodies which produce these *ideas* in our minds, are to be distinguished into *primary* and *secondary*. *Primary qualities* are such as are utterly inseparable from the body, in what state soever it be, and such as our senses continually find in every particle of matter; which are solidity, extension, figure, mobility, and the like. *Secondary qualities* are, such as are, in reality, nothing in the objects themselves, but only powers to produce various sensations in us, by means of their primary qualities; that is, by the figure, bulk, texture, &c. of their particles; as colours, sounds, taste, &c.

Now the *idea* of primary qualities are, in some sense, resemblances of them, and their powers do really exist in the bodies themselves; but the *idea* produced in us by those secondary qualities have no resembling of them at all. There is nothing like our *ideas* existing in the bodies themselves, that excite them; they are, in the bodies, as dissimiles from them, while it serves to produce those sensations in us, and what it serves, warm, blue, &c. in the *idea*, is no more than the bulk, figure, and motion, of the particles of the bodies themselves, which we call so.

The mind has several faculties of managing these simple *ideas*, which are worthy of notice; as, 1. That of discerning justly, and distinguishing rightly, between one and another, in which consists the accuracy of judgment.

2. That of comparing them one with another, in respect of extent, degree, time, place, or any other circumstances of relation or dependence, one on another.

3. That of composing, or putting together, the simple *ideas* received by sensation and reflection, in order to make complex ones.

4. Children, by repeated sensations, having got some *ideas* fixed in their memories, by degrees learn the use of signs; and when they can speak articulately, they make use of words, to signify their *ideas* in others.

Hence, the use of words being, so fixed as outward marks of our internal *ideas*, and these *ideas* being taken from particular things, if every particular idea that we take in should have a particular name annexed to it, names would become endless. To prevent this inconvenience, the mind has another faculty, whereby it can make the particular *ideas* received from such objects, become general;

which is done by considering them as they are in the mind; such appearances, separate from all other differences, and circumstances of existence, as time, place, and other concomitant *ideas*; and this is called *abstraction*, whereby *ideas*, taken from particular things, become general representatives of all of that kind, and their names, general names, applicable to whatever exists conformable to such abstract *ideas*. Thus, the same colour being observed to-day in chalk, or snow, which we observed yesterday, in paper, or milk, we consider that appearance alone makes it a representative of all of the same kind, and give it the name of *whiteness*; by which sound we always signify the same quality, whether to be met with, or imagined.

From the powers of combining, comparing, and separating, or abstracting simple *ideas*, acquired by sensation and reflection, all our complex *ideas* are formed; and, as before, in the perception of *ideas*, the understanding was passive, so here it is active, exerting the power it hath in the several acts and faculties above mentioned, in order to frame compound *ideas*.

Ideas, simple, though their number be infinite, and their variety endless, yet may all be reduced to these three heads; viz. *modes*, *substances*, and *relations*. *Modes* are such complex *ideas*, as, however compounded, are not supposed to exist by themselves, but are considered as dependences on, or affections of, substances: such are the *ideas* signified by the words *triangle*, *gratitude*, *murder*, &c.

These are of two kinds: 1. Such as are only variations, or different combinations, of the same simple *idea*, without the mixture of any other; as a dozen, a fovee &c. which may be called *simple modes*. 2. There are others, compounded of simple *ideas*, of several sorts put together, to make one complex one; as *heaven*, *light*, &c.

Substances have their *ideas* from such combinations of simple *ideas*, as are taken to represent distinct particular things subsisting by themselves; in which the supposed or confused *idea* of substance, such as it is, is always the first and chief.

Relations are a kind of complex *idea*, arising from the consideration or comparison of one *idea* with another. Of these, some only depend on the equality or excess of the same simple *idea* in several subjects; and these may be called *proportional relations*, such as *equal*, *more*, *bigger*, *smaller*, &c.

factum. Another occasion of comparing things together is owing to the circumstances of their origin and beginning; which not being afterwards to be altered, make the relations depending thereon as lasting as the subjects to which they belong. Thus it is with natural relations, as *father, mother, uncle, cousin, &c.* Thus also it is with relations by institution, as *prince and people, general and army, &c.* As to moral relations, they are the conformity or disagreement of men's free actions to laws and rules, whether human or divine. Further, *ideas* may be divided into *clear, or distinct*; and *obscure, or confused*.

IDEAS, simple, are *clear*, when they continue such as the objects present them to us when our organs of sensation are in good tone and order; when our necessities retain them; and can produce and present them to the mind whenever it has occasion to consider them; and when, with this, the mind sees that these simple *ideas* are essentially different one from another. The contrary to which is what we call *obscure and confused ideas*.

A *distinct idea* is that wherein the mind perceives a difference from all others; and a *confused idea* is such a one as is not sufficiently distinguishable from another, with regard to which it ought to be different.

Again, *ideas*, with respect to the objects whence they are taken, or which they are supposed to represent, come under a threefold distinction; being either *real, or fantastical, true, or false, adequate, or inadequate*.

By *real IDEAS* are meant, such as have a foundation in nature; such as have a conformity with the real being or existence of things, or with their archetypes.

IDEAS, fantastical or chimerical, are such as have no foundation in nature, nor any conformity with that being to which they are related, or with their archetypes. All our simple *ideas* are real; not that they are images or representations of what does exist, but as they are the certain effects of powers in things without us, obtained by our Maker to produce in us such sensations. They are *real ideas* in us, because that by them we distinguish the qualities that are really in the bodies themselves; their reality lies in the steady correspondence they have with the distinct constitutions of real being; but whether with those constitutions as causes or patterns; it matters not, so long as they are constantly produced by them.

As to complex *ideas*, in regard they are arbitrary combinations of simple *ideas* put together, and united under one general name, in forming whereof the mind uses its own liberty, some are found *true*, and some *imaginary*. 1. Mixed modes and relations, having no other reality than what they have in the minds of men, are really something more being required to their reality, but a possibility of existing conformable to them. These *ideas*, being themselves archetypes, cannot differ from their archetypes, and so they cannot be chimerical, unless any one jumbles inconsistent *ideas* in them; in which case, those that have names assigned to them, ought to have a conformity to the ordinary signification of these names, to prevent their appearing fantastical. 2. Our complex *ideas* of substances being made in reference to things existing without us, whose representations they are thought to be, are no farther real than as they are combinations of simple *ideas* really united and coexisting in things without us. Those are fantastical that are made up of several *ideas* that never were found united, as *centaur, &c.*

Real ideas are divided into *adequate*, and *inadequate*. **IDEAS, adequate**, are those which perfectly represent those archetypes which the mind supposes them taken from, and which it makes them stand for.

IDEAS, inadequate, are such as do but partially, or incompletely, represent those archetypes to which they are referred.

IDEAS, as to true and false, it may be observed, that truth and falsehood, in propriety of speech, belong only to propositions; and when *ideas* are referred *true or false*, there is some tacit proposition, which is the foundation of that denomination. Our *ideas* being nothing else but appearances or perceptions in the mind, can no more be said to be true or false, than single names of things can be said to be so; for truth and falsehood lying always in some affirmation or negation, no *idea* are not capable of them, till the mind passes some judgment of them. In a metaphysical sense they may be said to be true; i. e. to be really as they exist; i. e. thought in things called *true*, even in that sense, there seems to be a tacit inference to our *ideas*, looked upon as the standards of that truth, which amounts to mental proposition. When the mind refers its *idea* to any thing extraneous to it, they are then capable of being true or false; because, in such a reference, the mind makes a tacit proposition of their conformity to that thing; and as this proposition is true or false, so the *idea* themselves come to be denominated. Locke's Essay, Sec. vol. 1, passim.

IDENTITY *mainly*, a *wait* which lies for him who, upon a capax or exigent, is *unchanged*, and committed to reason, for another man or the same man.

IDENTITY, *formally*, that by which a thing is itself, and not any thing else. In which sense, *identity* differs from *similitude*, as well as *identity*.

Our *idea* of *identity* we owe to that power which the mind has of comparing the very being of things; whereby, considering any thing as existing at any certain time and place, and comparing it with itself as existing at any other time, &c. are accordingly pronounce it the same.

When we see any thing in any certain time and place, we are sure it is that very thing, and can be no other, how the fewer it may be to functioning else in all other respects; because we conceive it impossible, that two things of the same kind should exist together in the same place, we conclude, that whatever exists any where at the same time, excludes all of the same kind, and is at there itself alone. When, therefore, we demand, whether any thing be the same or no, it refers always to something that existed at such a time, in such a place; which it was certain, at that instant, was the same with itself, and no other.

We have *ideas* of three sorts of substances: of God, of finite intelligences, and of bodies. God being eternal, unchangeable, and every where, concerning his *identity* there can be no doubt. Finite spirits having had their determinate place, and time of beginning to exist, the relation to that time and place will always determine to each its *identity* as long as it exists. And the same will hold of every particle of matter to which no addition, or from which no subtraction, it made. These three exclude not one another out of the same place; yet each exclude those of the same kind out of the same place. The *identity* and diversity of modes and relations is determined after the same manner that those of substances are; only the actions of finite beings, as motion and thought, consisting in succession, cannot exist in different times and places as permanent beings; for no motion or thought, considered as at different times, can be the same; each part thereof having a different beginning of existence. From whence it is plain, that existence itself is the *principle of individuation*, which determines a being to a particular time and place incommunicable to two beings of the same kind.

Thus, suppose an atom existing in a determined time and place, it is evident, that, considered in any instant, it is the same with itself, and will be so, as long as its existence continues. The same may be said of two, or more, or any number of particles, which they continue together, the mass will be the same, however jumbled; but if one atom be taken away, it is then not the same mass. But in vegetables the *identity* depends not on the mass, and is not applied to the same thing; the reason of this is, the difference between an inanimate body, and a crude mass of matter; this latter being only the collection of particles any how united, the other such a disposition or organization of parts, as is fit to receive and distribute nourishment, so as to continue and frame the wood, bark, leaves, &c. (of an oak, for instance) in which consists the vegetable life. That, therefore, which hath such an organization of parts, partaking of one common life, continues to be the same plant, though that life be communicated to new particles of matter vitally united to the living plant. The case is not so much different in brutes, but that any one may hence see what makes an animal, and continues it the same. The *identity* of the same man likewise consists in a participation of the same continued life, in succeeding particles of matter vitally united to the same organized body.

To understand *identity* rightly, we must consider what *idea* the word stands for; it being one thing to be the same substance; another, the same man; and a third, the same person. An animal is a living organized body; and the same animal is the same continued life communicated to different particles of matter, as they happen successively to be united to that organized living body; and our notion of man is but of a particular sort of animal. Person stands for an intelligent being, that reasons and reflects, and can consider itself the same thing in different times and places, which it doth by that consciousness that is inseparable from thinking. By this every one is to himself, what he calls *self*, without considering whether that self be continued in the same, or in diverse substances. In this consists personal *identity*, or the immutability of a rational being; and so far as this consciousness extends backward to any past action, or thought, so far reaches the *identity* of that person. It is the self same now it was then; and it is by the same self, with this present one, that now reflects on it, that that action was done. Self is that conscious thinking thing, whatever substance it matters not, which is conscious of pleasure and

and pain, capable of happiness or misery; and so is concerned for itself, as far as that consciousness extends. That with which the consciousness of this present thinking can join itself, makes the same person, and is one felt with it, and is attributed to itself, and owns all the actions of that thing as its own, as far as that consciousness reaches.

Consciousness, says the excellent bishop Butler, of what is past, ascertain our personal identity to ourselves; yet to far that it makes personal identity, or is necessary to our being the same person, is to say, that a person has not existed a single moment, nor done one action, but what he can remember: indeed, none but what he reflects upon. And one should really think it self-evident, that consciousness of personal identity presupposes, and, therefore, cannot constitute, personal identity; any more than knowledge, in any other case, can constitute truth, which it presupposes. Though present consciousness of what we at present do and feel is necessary to our being the same person as we now are; yet present consciousness of past actions or feelings is not necessary to our being the same person who performed those actions, or felt those feelings. The identity of persons cannot subsist with diversity of substance; personal identity is, therefore, as Mr. Locke expresses it, the sameness of a rational being; and the question, whether the same rational being is the same substance, needs no answer: because being and substance, in this case, stand for the same idea. Consequently, though the successive consciousness which we have of our own existence are not the same, yet they are consciousness of one and the same thing or object; of the same person, felt, or living, *spirit*. The person of whose existence the consciousness is felt now, and was felt an hour or a year ago, is discerned to be, not two persons, but one and the same person; and, therefore, is one and the same. Butler's Analogy, Appendix, Diff. 1.

This personal identity is the object of reward and punishment, being that by which every one is concerned for himself. If the consciousness went along with the little finger; when that was cut off, it would be the same self, that was just before concerned for the whole body. If the same Socrates, waking and sleeping, did not partake of the same consciousness, he would not be the same person: Socrates waking could not be, in justice, accountable for what Socrates sleeping did; no more than one rein, for what his brother twin did; because their consciences were to him, that they could not be distinguished.

But suppose I wholly lose the memory of some parts of my life, beyond a possibility of retrieving them, so that I shall never be conscious of them again; am I one again the same person that did those actions, though I have forgot them? I answer, we must here take notice what the word *I* is applied to, which in this case is the man only; and the same man being presumed to be the same person, *I* is easily here supposed to stand also for the same person. But if it be possible for the same man to have a distinct, incommunicable consciousness at different times, it is just doubt the same man would, at different times, make different persons: which we see in the sense of mankind in the solemn declaration of their opinions; human laws not punishing the madman for the sober man's actions, nor the sober man for what the madman did; thereby making them two persons.

Thus we say, in English, such a one is not himself, or is before himself, in which phrase *I* is understood, that *I* is changed, and the self same person is no longer in that state. But is not a man drunk or sober, the same person? Why else is he punished for the same fact he commits when drunk, though he be never afterwards conscious of it? Just as much the same person, as a man that walks, and does other things in his sleep, is the same person, and is answerable for any mischief he shall do in it. Human laws punish with a justice suitable to their way of knowledge; because in these cases they cannot distinguish certainly what is real, and what is counterfeited; and to the ignorance in drunkenness, or sleep, is not admitted as a plea. For though punishment be annexed to perjury, and personality to consciousness, and the drunkard is not conscious, perhaps, of what he did, yet human judicatures justly punish him, because the fact is proved against him; but want of consciousness cannot be proved for him. But in the great day, when in the secrets of all hearts shall be laid open, it may be reasonable to think no one shall be made to answer for what he knows nothing of, but shall receive his doom; his own conscience accusing, or else excusing him.

To conclude this article: whatever substance begins to exist, it must, during its existence, be the same; whatever composition of substances begin to exist, during the union of those substances, the concrete must be the same. Whatever mode begins to exist, during its existence it is the same; and so is the composition be of distinct sub-

stances, and different modes, the same rule holds. Whence it appears, that the difficulty or obscurity that has been about this matter, rather arises from names ill used, than from any obscurity in the things themselves. For whatever makes the feasible idea, to which the same is applied, if that idea be flexibly kept to, the distinction of any thing into the same and diverse, will easily be conceived. Locke's Essay, vol. I. chap. 27.

IDEOT: See IDIOT, and LUNATIC.

IDES, *Idus*, in the Roman Calendar, a denomination given to eight days in each month; commencing in the months of March, May, July, and October, on the fifteenth day; and in the other months on the thirteenth day; and reckoned backward, to, at in the four months above specified to terminate on the eighth day, and in the rest on the sixth.

The origin of the word is contested. Some will have it formed from *dis*, *telus*, because the full moon was commonly seen on the day of the *Idus*, others from *idus*, *spatiositas*, on account of the large of the full moon then visible; others from *iduum*, or *idui* *idui*, a name given by the Hetrurians to a victim offered on that day to Jupiter; others from the Hetrurian word *idus*, i. e. *divides*, because the *Idus* divided the moon into two nearly equal parts.

The *Idus* name between the calendar and the names.

The 15th day in March, May, July, and October, and the 13th of the other months, being called the *Idus* of those months—*Idus Martii*, *Idus*, &c. the fourteenth day of the same four months, and the 12th of the other eight, were *nonas Idus*, or the eve of the *Idus* of March, &c. the 13th day in the four months, and the 11th in the eight, was called the third of the *Idus* of such months, 3 *Idus Martii*, &c. to the 12th day in the four, and the 10th in the eight months, were the 4th of the *Idus*, 4 *Idus Martii*, &c. and thus of the rest, to the 8th and 6th days, which made the 8th of the *Idus*, 8 *Idus Martii*, &c.

This way of accounting is still in use in the Roman chancery, and in the calendar of the hierarchy. The *Idus* of May were consecrated to Mercury; the *Idus* of March were always esteemed unhappy, after *Caesar's* murder; the time after the *Idus* of June was reckoned fortunate for those who entered into matrimony; the *Idus* of August were consecrated to Diana, and were observed as a feast day by the slaves; on the *Idus* of September, auguries were taken for appointing the magistrates, who formerly entered into their offices on the *Idus* of May, and afterwards on those of March.

IDIOM, *Idioma*, propriety, of *idus*, *propr*, own, is sometimes used for the peculiarities of a language; sometimes for a dialect, or the language of some particular province; differing, in some respects, from the language of the nation in general, whence it is derived.

IDIOMA, communication of. See COMMUNICATION.

IDIOPATHY, *Idiopathia*, derived from *idus*, *propr*, particular, and *pathos*, *passio*, affection, a disease, or indisposition, peculiar to some member, or part of the body, not caused by any other disease, or preceding affection; nor having any dependence on the rest of the body.

In which sense it stands opposed to *sympathy*, which is when the indisposition takes its rise from some prior disorder in some other part of the body.

Thus a cancer in the eye is an *idiopathy*; an epilepsy is either *idiopathy*, or *sympathy*; *idiopathy*, when it happens purely through some fault in the brain; *sympathy*, when it is provoked by some other disorder.

IDIOSYNCRASY, from *idus*, *propr*, own, and *synchro*, *mixtura*, *temperamentum*, is *Physic*, a temperament peculiar to some body, in consequence whereof, whether in sickness, or in health, it has a more than ordinary aversion, or inclination, to certain things, or is more affected with them than others usually are.

IDIOT, or IDIOT, in the English Language, denotes a natural fool, or a fool from his birth.

The word is originally Greek, *idiotis*, which primarily imports a private person, or one who leads a private life, without any share or concern in the government of affairs.

A person who has understanding enough to measure a yard of cloth, number twenty rightly, and tell the days of the week, &c. is not an *idiot* in the eye of the law. But a man who is born deaf, dumb, and blind, is considered by the law in the same state as an *idiot*.

IDIOT, *idiotis*, is also used, by ancient writers, for a person ignorant, or unlearned; answering to *idiotus*, or *imperitus*. In this sense, Victor tells us, in his Chronicon, that, in the consilium of Nestas, the holy Gospels, by command of the emperor Anastasius, were corrected and amended, as having been written by *idiot* evangelists: *Tamquam ab idiotis evangelistis composita*.

IDIOTA *inquiritur* vel *examinatur*, a writ issued out of the sheriff

sheriff of a county, where the king has notice that there is an *idiot* naturally born, to weak of understanding that he cannot govern or manage his inheritance; directing him to call before him the party suspected, and examine him, and enquire, by a jury of twelve men, whether he be an *idiot*. For the king, by his prerogative, has the government of the lands and substance of such as are naturally defective in their discretion.

This branch of the revenue hath been long considered as a hardship upon private families; but few instances occur of the oppressive exertion of it.

IDIOSM, derived from *idios*, *proprie*, *peculiar*, in Grammar, a phrase, or manner of speaking, peculiar to a language, and which cannot be rendered word for word into any other.

Idiosm is defined, by some authors, an inflection of some verb, or a particular construction of some phrase or particle that is anomalous, and deviates from the ordinary rule of the language of the nation, but which is in use in some particular province of it.

Several authors have written of the *idiosm* in the Greek and Latin languages; that is, of the particular turns in those tongues which vary the most from each other, and from the more popular among the modern tongues; but the examples of these *idiosms* being borrowed from the best authors, *idiosm*, in this sense, cannot properly be called an irregularity.

IDLENESS, in Law. See VAGABOND.

IDOL, from *eidolon*, which signifies the same, of *idos*, *image*, *figure*, a statue or image of some false god, to whom divine honours are paid, altars and temples erected, and sacrifices offered.

The *idos* or image, whatever materials it consisted of, was, by certain ceremonies, called consecration, converted into a god. While under the artificer's hands, it was only a mere statue.

Three things were necessary in order to change it into a god; proper ornaments, consecration, and oration. The ornaments were various, and wholly designed to blind the eyes of the ignorant and stupid multitude, who are chiefly taken with show and pageantry. Then followed the consecration and oration, which were performed with great solemnity among the Romans.

IDOLATRY, from *ειδωλατρον*, which signifies the same, composed of *idos*, *image*, and *latreia*, is *service*, the worship and adoration of false gods; or the giving those honours to creatures, or the works of men's hands, which are only due to God.

Several have written of the origin and causes of *idolatry*; among the rest, Voltaire, Selden, Godwyn, and Tennison; but it is still a doubt who was the first author of it. It is generally allowed, however, that it had not its beginning till after the deluge; and many are of opinion, that Belus, who is supposed to be the same with Nimrod, was the first man that was deified.

But whether they had not paid divine honours to the heavenly bodies before that time, cannot be determined; our acquaintance with these remote things being extremely slender.

All that can be said with certainty is, that 426 years after the deluge, when God led Terah and his family out of Chaldaea, and Abraham passed over Mesopotamia, Canaan, the kingdom of the Philistines, and Egypt, it does not appear that *idolatry* had then got any footing in any of those countries; though some idly pretend, that Abraham himself was an idolater.

The first mention we find made of it is, in Gen. xxxi. 19. where Rachel is said to have taken the idols of her father: for though the meaning of the Hebrew word *TERAPHIM* תְּרָפִים is disputed, yet it is pretty evident they were idols. Laban calls them his gods, and Jacob calls them strange gods, and looks on them as abominations.

The original of *idolatry*, by image worship, is by many attributed to the age of Eber, about 401 years after the deluge; though most of the fathers place it no higher than that of Serus; which seems to be the more probable opinion, considering that for the first 134 years of Eber's life all mankind dwelt in a body together; during which time it is not reasonable to suppose, that *idolatry* broke in upon them; then some time must be allowed after the dispersal of the several nations, which were but small at the beginning, to increase and settle themselves: so that if *idolatry* was introduced in Eber's time, it must have been towards the end of his life, and could not well have prevailed to universality, and with that obstinacy, which some authors have imagined. The authors of the Universal History think, that the origin and progress of *idolatry* is plainly pointed out to us in the account which Moses gives of Laban's and Jacob's parting, Gen. xxxi. 44, &c. From the custom once introduced of erecting monuments in memory of any solemn covenants, the

transition was easy into the notion, that some deity took its residence in them, in order to punish the first aggressors; and this might be soon improved by an ignorant and degenerate world, till not only birds, beasts, stocks, and stones, but sun, moon, and stars, were called into the same office, though used, perhaps, at first, by the designing part of mankind, as scare-crows, to overawe the ignorant. Univ. Hist. vol. i. part ii. p. 853. edit. fol.

Cluverius, German. Antiq. lib. i. maintains Cain to have been the first idolater; and the false gods that he worshipped to have been the stars, to whom he supposed God had left the government of the lower world: but this is mere conjecture.

Sanchoniathon, who wrote his Phœnician Antiquities, apparently with a view to apologize for *idolatry*, traces its origin to the descendants of Cain, the elder branch, who began with the worship of the sun, and afterwards added a variety of other methods of idolatrous worship; proceeding to deify the several parts of nature, and men after their death, and even to consecrate plants shooting out of the earth, which the first men judged to be gods, and worshipped, as those that sustained the lives of themselves and of their posterity. Cumberl. on Sanchon. p. 319, &c.

The Chaldean priests, in process of time, being by their situation early addicted to celestial observations, instead of conceiving as they ought to have done concerning the omnipotence of the Creator and mover of the heavenly bodies, fell into the impious errors of esteeming them as gods, and the immediate governors of the world, in subordination, however, to the Deity, who was invisible, except by his works, and the effects of his power. Concluding that God had created the stars, and great luminaries, for the government of the world, partakers with himself, and as his ministers, they thought it but just and natural that they should be honoured and extolled, and that it was the will of God they should be magnified and worshipped. Accordingly they erected temples, or *zikkurats*, to the stars, in which they sacrificed and bowed down before them, esteeming them as a kind of mediators between God and man. Impostors afterwards arose, who gave out, that they had received express orders from God himself concerning the manner in which particular heavenly bodies should be represented, and the nature and ceremonies of the worship which was to be paid them. When they proceeded to worship wood, stones, or metal, formed and fashioned by their own hands, they were led to apprehend, that these images had been, in some way or other, animated or informed with a supernatural power, by supernatural means; though Dr. Pridemore imagines, that, being at a loss to know how to address themselves to the planets when they were below the horizon, and invisible, they resorted to the use of images. Dr. Pridemore's Connection, &c. book iii. p. 177, 8vo.

But it will be sufficient to suppose, that they were persuaded that each star or planet was actuated by an intelligence; and that the virtues of the heavenly body were infused into the image that represented it. It is certain, that the sentient nature and divinity of the sun, moon, and stars, was strenuously asserted by the philosophers, particularly by Pythagoras and his followers, (Diogen. Laert. lib. viii. p. 509.) and by the Stoics (Cicero, De Nat. Deor. lib. ii. cap. 15.) as well as believed by the common people, and was indeed the very foundation of the pagan idolatry. The heavenly bodies were the first deities of all the idolatrous nations, were esteemed eternal, sovereign, and supreme, and distinguished by the title of the natural gods. Thus we find that the primary gods of the heathen in general were Saturn, Jupiter, Mars, Apollo, Mercury, Venus, and Diana: by which we can understand no other than the sun and moon, and the five greatest luminaries next to these. Plutarch expressly censures the Epicureans for asserting that the sun and moon are void of intelligence, whom all men worshipped. Ad. Colorem. p. 113.

Sanchoniathon (apud Euseb. Prep. Evan. lib. i. cap. 9.) represents the most ancient nations, particularly the Phœnicians and Egyptians, as acknowledging only the natural gods, the sun, moon, planets, and elements; and Plato declares it as his opinion, that the first Grecians likewise held these only to be gods, as many of the barbarians in his time did. In Cratyl. p. 273. F. See also Herodot. lib. i. cap. 131. 138. lib. iii. cap. 16. Diocl. Sic. lib. i. p. 10, 11. ed. Rhodm. Strab. Geogr. lib. xv. p. 732. Polyb. Hist. lib. vii. p. 699, 700. ed. Gronov. Euseb. Prep. Ev. lib. ii. cap. 2. p. 39. Even Philo (Lib. De Somniis) and Origen (in his books Πη Αρρη) maintain, that the stars are to many folk incorruptible and immortal. See Farmer on Miracles, chap. iii. § 2.

Besides these natural gods, the heathens believed, that there were certain spirits who held a middle rank between

the gods and men on earth, and carried on all intercourse between them; conveying the addresses of men to the gods, and the divine benefits to men. These spirits were called *dæmons*. From this imaginary office ascribed to them, they became the grand objects of the religious hopes and fears of the pagans, of immediate dependence and divine worship. In the most learned nations, they did not properly share, as in gross the public devotion. To these alone sacrifices were offered, while the celestial gods were worshipped only with a pure mind, or with hymns and praises. As to the nature of these *dæmons*, it has been generally believed, that they were spirits of a higher origin than the human race; and, in support of this opinion, it has been alleged, that the supreme deity of the pagans is called the greatest *dæmon*; that *dæmons* are defined as beings placed between the gods and men; and that *dæmons* are expressly distinguished from heroes, who were the departed souls of men. A late ingenious writer has with great acuteness and erudition combated this opinion, and maintained, on the contrary, that by *dæmons*, such as were the more immediate objects of the established worship amongst the ancient nations, particularly the Egyptians, Greeks, and Romans, we are to understand beings of an earthly origin, or such departed human souls as were believed to become *dæmons*. This, he says, is a fact attested by all antiquity, whether Pagan, Jewish, or Christian. He appeals to the testimonies of the heathen historians, poets, and philosophers, and to the nature of the worship paid to the heathen deities. He examines the authority of the Old Testament writers, of the authors of the Septuagint version, of Philo and Josephus, of the New Testament; and of the Christian fathers. For a farther view of the strictly manner in which this argument is treated, see Farmer on Miracles, chap. iii. § 2. postum. Farmer on Demoniacs, § 2. See Dæmon and Miracles.

Voltaire, in the 2^d. INOUE, Encyclopédie, labours to vindicate the heathens in general from the charge of idolatry. He says, that there has not existed any people on earth who assumed the name of idolaters: and that no such term is found in Homer, or Hesiod, or Herodotus, or any author of the pagan religion; and that no law was ever enacted, requiring the ultimate worship of idols. The Greeks and Romans, he says, were gentiles and polytheists, but not idolaters; they worshipped the gods by means of their images, and not the images themselves; and were no more chargeable with idolatrous worship than the votaries of the Romish church. He also extends his laboured and spirited vindication to the Persians, Babylonians, Egyptians, Tartars, and Turks; and observes, that it is an abuse of terms to call those people idolaters who worship the sun and stars, &c.

The principal causes that have been assigned for idolatry are, the indelible idea which every man has of God, and the evidence which he gives of it to himself; an inviolable attachment to the senses, and a habit of judging and deciding by them, and then only: the pride and vanity of the human mind, which is not furnished with simple truth, but mingles and adulterates it with fables; the ignorance of antiquity, or of the first times, and the first men, whereof we have but very dark and confused knowledge by tradition, they having left no written monuments or books; the ignorance and change of languages: the style of the oriental writings, which is figurative and poetical, and personifies every thing; the superstition, scruples, and fears, inspired by religion; the flattery of writers; the false relations of travellers; the fictions of poets; the imaginations of painters and sculptors; a smattering of physics, that is a slight acquaintance with natural bodies and appearances, and their causes; the establishment of colonies, and the invention of arts, mistaken by barbarous people; the artifices of priests; the pride of certain men, who have affected to pass for gods; the love and gratitude borne by the people to certain of their great men and benefactors; and finally the Scriptures themselves ill understood.

IDOLOPEGIA, *Idolopægia*, in *Rhetoric*, a species of *PROSOPOPEIA*, where dead persons are supposed to speak.

IDOLOTHYTA, *Idolothuta*, things offered in sacrifice to idols; concerning the use of which, the apostle Paul lays down rules in 1 Corinth. chap. viii. ver. 4, 7, and 10.

IDULIA, in *Idology*, certain eggs offered to Jupiter on the ides of every month. They were so called, from their being offered on the ides.

IDYLLION, in *Pædy*, a little poem, containing the description or narration of some adventures.

The word is derived from the Greek *ιδύλλιον*, diminutive of *ιδύω*, *figura*, representation; because this poetry consists in a natural lively image, or representation of things. Theocritus is the oldest author who has written *idyllions*. The Italians imitate him, and have brought the *idyllion* into modern use.

The *idyllions* of Theocritus have a peculiar delicacy; they appear with a clownish, rustic kind of simplicity, but are full of the most exquisite beauties; they form drawn from the breast of nature herself, and to have been dictated by the graces.

The *idyllion* is a kind of poetry which paints the objects as they describe; whereas the epic poem relates them, and the dramatic acts them. The modern writers of *idyllions* do not keep up to that original simplicity observed by Theocritus; the people of our days would not bear an amorous fiction, resembling the awkward gallantries of our peasants. Boileau observes that the shortest *idyllions* are usually the best.

The modern *idyllions* differ from those of the ancients, by introducing none but allegorical shepherds, or countrymen disguised in their dress; whereas those of the ancients represent true shepherds. Mr. Hardion observes, that the taste of the present age is so very different from that of the ancients in this respect, that he would not take upon him to give a literal translation of Theocritus's *idyllions*; not that he reckons them bad in themselves, nor that he condemns the rules followed in their composition; but because the rules that were good at the time those poems were written, would, in the present age, be nullified but by very few.

The subject of *idyllions*, as being low of itself, requires the greatest elegance of diction to set it off. Mr. Hardion is of opinion, that Theocritus has the advantage of Virgil in this respect; observing always the structure peculiar to pastoral poems which constitutes one of its chief beauties. This structure requires that the fourth foot of every verse should be a dactylus, and sometimes also the first, when it can be done without affectation. Besides, it is also necessary these dactyls should be made without any caesura following; and, if possible, there should be a rest in the sense after each dactyle, which would add greatly to the regularity and perfection of each verse. Such are the following verses of Theocritus and Virgil:

Εἴτε μιν, ἢ Κασίωνα, τοῖς αἰβάσι, ἔνα Φωσέτω.

Theoc. Idyl. iv. ver. 1.

Die mihi, Damata, injum pecus? de Melibee?

Virg. Ecl. iii. ver. 1.

This structure in pastoral poems gives a vivacity, which is wonderfully pleasing in the mouth of a shepherd. These rules are observed by Theocritus, with all the exactness possible; but by Virgil seldom, which is rather to be imputed to the genius of the Latin tongue than his want of ability; it being less copious, bold and pizant, than the Greek. Mem. Acad. Inscript. tom. vi. p. 255, 256.

The invention of the *idyllion* is ascribed to Daphnis, who by his extraordinary genius, says Diodorus Siculus, "invented the bucolic poem and song, in the form it continues to appear in at present, in Sicily." This passage is considerable, as it fully ascertains the origin of the *idyllion*, such as it appears in Theocritus, and those that have imitated him.

After Daphnis, another Sicilian shepherd, called Dinnus, made himself famous for his pastoral poems. Next came Sicleschorus, who, according to Aelian, was the first that made the misfortune of Daphnis the subject of his songs. He lived, as some chronologists will have it, in the time of Phalaris, about 550 years before the vulgar æra; and lastly, some ages after this, Theocritus appeared, who forming himself on these first models, so far excelled, as to give pastoral poetry all the perfection it was capable of receiving. Mem. Acad. Inscript. tom. ix. p. 101.

JEALOUSY, in *Ethics*, is that peculiar uneasiness which arises from the fear that some rival may rob us of the affection of one whom we greatly love, or suspicion that he has already done so. The first sort of *jealousy* is inseparable from love, before it is in possession of its object: the latter is often unjust, generally mischievous, always troublesome.

JEALOUSY, *notus* of. See WATER.

JEAN-CAPELLE, in *Idyllography*, a name given by Ruyssch, and some others, to the fish called by authors the *fisher Indicus*, or *Indian BORER*; and more expressively named by Aristi the ZEUS with a forked tail.

JECARINUS, *pisces*, in *Idyllography*, a name given by Gaza, and many other writers, to the fish more commonly called *HEPATUS pisces*, by some *jeur marinus*.

JECTIGATION, in *Physic*, a trembling, palpitation, or disorderly and convulsive motion of the whole body, of one side, or only of the heart and pulse of a sick person: this shews that the brain, which is the origin of the nerves, is attacked, and threatened with convulsions.

JECUR. See LIVER.

JECUR MARINUM, in *Idyllography*, is used by Hermolaeus and some other writers in the same sense with *HEPATUS*.

JECTR. strivum. The *PLACENTA* is by some thus called, from the supposed similitude of its figure and office with that of the liver.

JEER. capitan. See *CAPTAIN*.

JEERS, or JEARS, in a Ship, an assemblage of tackles, by which the lower yards of a ship are hoisted up along the mast to their usual station, or lowered from thence as occasion requires; the former of which operations is called *raising*, and the latter *striking*.

In a ship of war, the *jeers* are usually composed of two strong tackles, each of which has two blocks, viz. one fastened to the lower mast-head, and the other to the middle of the yard. The two blocks which are fastened to the middle, or flings of the yard, are retained in this situation by means of two cleats, nailed on each side, whose arms include the ropes by which the blocks are fastened to the yard. The two ropes which communicate with these tackles lead down to the deck on the opposite side of the mast, according to the situation of the upper *jeer-blocks*. The *jeers* in merchant-ships have usually two large single blocks on the opposite side of the mast-head, and another of the same size in the middle of the yard. The rope which communicates with these, passes through one of the blocks hanging at the mast-head, then through the block on the yard, and afterwards through the other hanging block upon the mast. To the two lower ends of this rope, on the opposite sides of the mast, are fixed two tackles, each of which is formed of two double blocks, the lower one being hooked to a ring-bolt in the deck, and the upper one spliced or seized into the lower end of the great rope above, which is called the *eye*. By this contrivance the mechanical power of the tackle below is transmitted to the *eye*, which, communicating with blocks on the yard, readily *ways up* or *lowers it*, either by the effort of both *jeers* at once, on the opposite sides of the mast, or by each of them separately one after another. Valcour.

They say a man is brought to the *jeers*, when going to be punished at the *jeer-capsion*. This is done in the following manner: a capstan-bar being thrust through the hole of the barrel, the offenders arms are extended at full length cross-wise, and so tied to the bar; having sometimes a basket of bullets, or some other like weight, hanging by his neck. In this posture he continues till he is either brought to confess some plot or crime, whereof he is suspected; or that he has suffered what he is sentenced to undergo, at the discretion of the captain.

JEHOAH. See *GIAOH*.

JEHOVAH, in Theology, one of the scripture names of God; signifying the being who is self-existent, and who gives existence to others. See *GOD*.

So great a veneration had the Jews for this name, that they left off the custom of pronouncing it; whereby its true pronunciation was forgotten. They call it *TETRAGRAMMATON*, or the name with four letters; and believe that whoever knows the true pronunciation of it, cannot fail to be heard by God.

JEJUNE. Ake. See *STYLE*.

JEJUNUM, the second of the small guts; thus called from the Latin *jejunus, hungry*; because always found empty. See *INTESTINES*.

JELLAL-EAN, or GELAL-EAN calendar, epocha, and year. See *CALENDAR, EPOCHA, and YEAR*.

JELLY, a form of food, or medicine prepared from the juice of ripe fruits, boiled to a proper consistence with sugar, or of the strong decoctions of the horns, bones, or extremities of animals, boiled to such a height as to be stiff and firm when cold, without the addition of any sugar.

The *jellies* of fruits are cooling, saponaceous, and astringent, and therefore are good as medicines in all disorders of the primæ viæ, arising from acalefcent juices, especially when not given alone, but diluted with water. On the contrary, the *jellies* made from animal substances are all acalefcent, and are therefore good in all cases in which an acidity of the humours prevails: the acalefcent quality of these is, however, in a great measure taken off, by the adding lemon juice and sugar to them. They were formerly a sort of *jellies* much in use, called *compounded jellies*; these had the restorative medicinal drugs added to them, but they are now scarce ever heard of.

JELLY, wet, a preparation of common oint, recommended by many of the German physicians in all hectic disorders, to be taken with bread of fruits or crag-fish.

It is made by boiling a large quantity of oars, with the husk taken off, with some hard-boiled havings, and currants together, with a leg of veal cut in pieces, and with the bones all broken; these are to be set over the fire with a large quantity of water, till the whole is reduced to a fort of *jelly*, which, when strained and cold, will be very firm and hard. A few spoonfuls of this are to be taken every morning, diluted with a basin of either of the mentioned broths, or any other warm liquor.

JEMBUT, in the Materia Medica, a name used by Avicenna and others, to express the seeds in the pails of the carob-tree, or *siquis dulcis*; which they call *chirub* or *churnub*, and the Greeks *ceratium*.

JENDAYA, in Ornithology, the name of a Brazilian species of paroquet. It is of the size of a black bird; its beak and legs are black, and its back, wings, and tail, are of a bluish green; the tips of its wings are blackish, and its head, neck, and breast, are of a pale yellow, with an admixture of a deeper yellow in some places. Margrave.

JENNET, in Hierarchy. See *HORSE*.

JENNY worm. See *WORM*.

JENTLING, in Ichthyology, the name of a river fish caught in the Danube, and most of the great rivers in Germany, and called by the Germans *schind, schint, jent, and kopten*; and by Gesner *capit carolus*, the blue chub.

JEOPAILE, 1809 A.D., in Law, a compound of three French words *je en jadis, I have failed*. It is used in a legal sense, when the parties to any suit have, in pleading, proceeded so far, that they have joined issue, which shall be tried, or is tried by a jury, and this pleading or issue is badly joined, so that it will be error if they proceed.

In this case, one of the parties might, by their counsel, shew it to the court, as well after verdict given as before the jury was charged, by saying, *This inquiry you ought not to take, or, To judgment you ought not to go*. But this occasioning great delays in suits, for the redress thereof several statutes were made; viz. 32 Hen. VIII. cap. 30. by which it is enacted, "That if the jury have once passed upon the issue, though afterwards there be found a *jeopail* in the pleading, yet shall judgment be given according to the verdict of the jury." Other statutes have also been made relating to the same thing, in the time of queen Elizabeth and king James I.

The 18th Eliz. cap. 14. ordains, that after verdict given in any court of record, there shall be no stay of judgment or reversal, for want of form in a writ, *costs*, &c. or for want of any writ original or judicial; or by reason of insufficient returns of *fiat*, &c. But this is not to extend to appeals of felony, indictments, &c. By 21 Jac. I. cap. 13. if a verdict shall be given in any court of record, the judgment shall not be stayed or reversed for variance in form between the original writ or bill, and the declaration, &c. or for want of averment of the party's being living; or because the *venue faciat* is in part misawarded; for misnomer of jurors; want of return of writs; or because the return officer's name is not set to the return, &c. The 1st 16 & 17 Car. II. cap. 8. enacts, that judgment shall not be stayed or reversed after verdict in the courts of record at Westminster, &c. for default in form; or because there are not pledges to prosecute upon the return of the original writ, or because the name of the sheriff is not returned upon it; for default of alleging the bringing into court of any bond, &c. or for the omission of *et al.* or *contra pacem*; making the Christian name or surname of either party, or the sum of money, day, month, or year, &c. in any declaration or pleading being rightly named in any record, &c. preceding, &c. &c. But all such defects as are against the right of the matter of the suit, or whereby the issue or trial are altered, shall be amended by the judges, though not in suits of appeal, or felony, indictments, informations on penal statutes, which are excepted out of the act. The 22 & 23 Car. II. cap. 4. made this act perpetual. By 4 & 5 Ann. cap. 16. all the statutes of *jeopails* shall extend to judgments, entered by confession, *nil dicit*, or *non sum informatus*, in any court of record; and no such judgment shall be reversed, nor any judgment or writ of inquiry of damages thereon shall be stayed, for any defect which would have been added by those statutes, if a verdict had been given; so as there had been an original writ filed, &c. The 5 Geo. I. cap. 13. ordains, that, after verdict given, judgment shall not be stayed or reversed for defect in form or substance, in any bill or writ, or for variance therein, from the declaration, or any other proceedings.

JERBOA, in Zoology, is made a distinct genus of animals by Mr. Pennant, with two cutting teeth in each jaw, two very short fore-legs, two very long hind-legs, resembling those of cloven-footed water-fowl, and a very long tail, tufted at the end. This genus comprehends the *mus jerboa* of Linnaeus, inhabiting Egypt, Barbary, Palestine, and the deserts between Babelone and Aleppo; the *mus leprosus*, inhabiting the torrid zone; the *Siberian jerboa*, or flying hare, called *alagaga*; and the Indian *jerboa*, or *le hupier* of Buffon, inhabiting India. The Egyptian *jerboa* is represented Tab. III. *Quadrupedæ*, N. 25.

JEREMIAH, in Scripture History, a canonical book of the Old Testament. This divine writer was of the race of the priests; the son of Hiliah of Anathoth, in the tribe

of Benjamin. He was called when very young to the prophetic office, about the thirtieth of Josiah; and continued in the discharge of it above forty years. He is said by St. Jerom, &c. to have been stoned to death by the Jews for preaching against their idolatry; but it is most likely that he died in Egypt, much advanced in years, and broken by the calamities which happened to himself and his country.

There were several collections of *Jeremiah's* prophecies; One made by God's command in the fourth year of Jehoiakim, chap. xxxi. 2. This contained all the prophecies he had published to that time, as well against the other nations as against the Jews. The former of these in the present collection are put by themselves at the end of the book from chap. xli. to the end of the lili. But in the present copies of the Septuagint they follow immediately after the thirteenth verse of the twenty-fifth chapter. Another collection of these prophecies, mentioned chap. l. 3. comprehends all those which *Jeremiah* had uttered to the time of the captivity, and were probably collected by Baruch, his amanuensis, and are put together without any regard to the order of time. To this was added another collection of prophecies, published about the time of his going down into Egypt, contained in chap. xlii. still, xlii. at the end of which Ezra, or some other, after the captivity, added these prophecies which *Jeremiah* delivered against the Gentiles. The fifty-second chapter was probably added by Ezra, and is chiefly taken out of the latter part of the second book of Kings, with additions, which Ezra might supply out of the public records. The book of *Jeremiah* is altogether written in Hebrew, except the eleventh verse of the tenth chapter which is Chaldee.

St. Jerom has observed upon this prophet, that his style is more easy than that of Isaiah and Hosea; that he retains something of the rusticity of the village where he was born; but that he is very learned and majestic, and equal to those two prophets in the sense of this prophetic.

JERALCON, the English name of the gyrfalco, a very fierce, bold, and large bird, the largest of all the falcon kind. See **GYRFALCON**.

JERGUER, in the *English House*, one who oversees the accounts and conduct of the waiters.

JERICHO, *city of*, in *Britany*. See **ANASTATICA**.

JERKIN, a name given by some to the male of the jersal-con. See **GYRFALCON**.

JERONYMITES, or **HIERONYMITES**, a denomination given to divers orders, or congregations of religious; otherwise called *Hermits of St. Jerom*.

The first, called *Hermits of St. Jerom* of Spain, owe their origin to the third order of St. Francis, whereof the first *Jeronymites* were members. Gregory the eleventh confirmed this order, under the name of St. Jerom, whom they had chosen for their patron, and their model; and gave them the constitutions of the convent of St. Mary of the Sepulchre, with the rule of St. Augustine; and for habit, a white tunic, with a scapulary, a little capuche, and a mantle all of a natural colour, without dying, and without a mean price.

The *Jeronymites* are in possession of the convent of St. Laurence, in the Eclesiastical, where the kings of Spain are buried.

In Spain there is likewise an order of nuns of St. Jerom, founded by a lady toward the close of the fifteenth century. Sixtus put them under the jurisdiction of the *Jeronymites*, and gave them the constitutions of the monastery of St. Martha of Cordova, which were afterwards changed by Leo X. for those of the order of St. Jerom.

Hermits of St. Jerom, of the Observance, or of Lombardy, were founded by Lupus d'Olmedo in 1424, in the mountains of Calabria, in the diocese of Seville.

The third order of *Jeronymites* was founded by Peter Gambacorti, about the 1377; but the vows they made were only simple, till 1568, when Pius V. appointed them to be solemn. They have houses in Tiro, Italy, and Bavaria.

The fourth congregation of *Jeronymites*, are the *Hermits of St. Jerom of Fiume*, begun in 1362, when Charles de Montegranchi, of the family of the count of that name, retiring into solitude, first established it at Verona. It was approved by Innocent VII. under the title and constitutions of St. Jerom. But Eugenius IV. changed it for that of St. Augustine. As the founder was of the third order of St. Francis, they preserved that habit; but, in 1460, Pius permitting such as pleased to change it, versed into a division among them. This order was finally suppressed by Clement XI. in 1663.

JERSEY, among *Westlanders*, denotes the finest wool, taken from the rest by dressing it with a *jersey* comb.

NEW JERSEY lies in *Batany*. See **CLANOVITUS**.

JERTH, in the *Materia Medica*, a name given to a certain kind of moss, according to Scheffer, growing very plentifully in Lapland, and other cold countries. The use of this is the part used in medicine, and the method of giving it is in decoction. They boil a large quantity of it in the whey made of rein deer's milk, and give the patient large draughts of it, warm, every hour or two; by that means keeping up a good perspiration, which they increase or diminish according to the nature of the case. The principal diseases to which they are subject are rheumatisms, and the small-pox; and it is wonderful to see how well they get through these two dangerous complaints by this regimen alone. And, upon these two, the virtues of so much warm and diluting liquor seem to be the principal thing to be depended upon by them; for they cannot readily get the *jerth* root, they scruple not to supply its place with the stalks of angelica, and the medicine seems to succeed as well this way as the other, both in the small-pox and other cases.

JERUSALEM *artichoke*. See **ARTICHOKE**.

JERUSALEM *crucifix*. See **LUNG-wort**.

JERUSALEM *salt*, a species of *chempodium*. See **GOOSE-fat**.

JERUSALEM *sege*. See **SAGISTREE**.

JESEN, in *Ichthyology*. See **JENTLING**.

JESILBASCH, *green-head*, a name of reproach which the Persians give to the Turks, because their emirs wear a green turban.

JESSANT, formed from the obsolete French *jessir*, to rise or spring out, in *Horology*, is applied to a heart-de-lys, or the like figure, seeming to spring or shoot out of some other charge. He bears fable; three leopard's heads; *jessant*, *hearts-de-lys*, &c.

JESSAMINE, or **JESAMINE**. See **JAMINE**.

JESSE, a large brass candlestick with many sconces hanging down, in the middle of a church or choir. This invention was first called *jesse*, from the similitude of the branches to those of the *arbut* *jesse*. This useful ornament of churches was first brought over into this kingdom by Hugh de Flori, abbot of St. Austin's in Canterbury, about the year 1100.

JESSES denote ribbons hanging down from garlands and crowns; also the throat straps of leather, fastened to a hawk's legs, and so to the velleys; and birds, in *Horology*, are said to be *jessed*, when their *jesses* are of a different disfigure from the other parts.

JESTING, or *convivis*, as distinguished from continued wit or HUMOR, lies either in the thought, or the language, or both. In the first case it does not depend upon any particular words or turn of the expression. But the greatest fund of jests lies in the language, i.e. in tropes or verbal figures; those afforded by tropes consist in the metaphorical sense of the words, and those of verbal figures principally turn upon a double sense of the same word, or a similitude of sound in different words. The third kind of jokes, which lie both in the sense and language, arise from figures of sentences, where the figure itself consists in the sense, but the wit turns upon the choice of the words. Ward's *Order*. vol. ii. Lect. 40.

JESUALES, **JESUALES**, an order of religious, otherwise called *Apocalyptic Clerks*, or *Jesuits of St. Jerom*.

They were founded by John Colombini, in 1368, and approved of by Urban V. in 1369, at Viterbo; where he himself gave, to such as were present, the habit they were to wear.—They followed the rule of St. Augustine, and were ranked by Pius V. among the order of Mendicants.

They were called *Jesuates*, because their first founders had the name of Jesus continually in their mouths: to which they added the name of St. Jerom, because they chose that him for their protector.

For two centuries the *Jesuates* were mere lay-brothers; but in 1666, Paul V. gave them leave to enter into holy orders.—In most of their houses they were employed in pharmacy, distributing their medicines gratis; others practised distillation, and sold aqua vitae; which occasioned their being called *apocryphic-mongers*.

Being very rich in the state of Venice, that republic solicited their suppression, and obtained it of Clement IX. in 1668, their effects being employed towards supporting the expences of the war in Candia.

JESUITES, an order of religious, founded by Ignatius Loyola, a Biscayan military gentleman, of a fanatical and ambitious spirit, called also the *Society of Jesus*. They are also sometimes called *Loyalists*, and sometimes *Ignatians*, from the Spanish name of their founder, which was *Sancho de Guzman*.

This order, which was the most political and best regulated of all the monastic orders, and from which mankind have derived more advantages, and received greater hurt, than from any other of their religious fraternities, has rendered itself very considerable by its millions into the

the Indies, and by its other employments relating to the study of the sciences, and the education of youth. The council of Trent calls them, *Regular Clerks of the Company of Jesus*.

In the year 1538, Ignatius, having assembled ten of his companions at Rome, chosen mostly out of the university of Paris, proposed to them to make a new order. After this, he presented the plan of his institution, suggested as he gave out, and his followers still teach, by the immediate inspiration of heaven, to Paul III. who appointed a committee of cardinals to examine it; upon whose reports, that the establishment was unnecessary as well as dangerous, Paul refused to approve it. This opposition was principally urged by the learned and worthy cardinal Guidicioni.

This opposition was vanquished by the dexterity of Ignatius, who proposed, that besides the three vows of poverty, chastity, and monastic obedience, the members of this society should take a fourth vow of obedience to the pope, binding themselves to go whithersoever he should command, for the service of religion, and without requiring any thing from the holy see for their support. However, Ignatius and his company in the same charter of their order in which they declare their implicit and blind allegiance to the court of Rome, promise a like implicit and unlimited allegiance to the general of their society. The pontiff, perceiving this institution to be an object of confidence, confirmed it, under the name of the *Company of Jesus*, by a bull in 1540, and appointed Ignatius Loyola to be the first general of the order. Loyola was originally an illustrious soldier, and is supposed by many to have been only a flexible instrument in the hands of able and ingenious men, who made use of his fortitude and fanaticism to answer their purposes, and persons much more learned were employed to compile the writings which bear his name. *Goddes's Tracts*, vol. iii. p. 429.

By this bull, their number was restrained to forty; but that restriction was taken away, two years afterwards, by another bull. The order has since been confirmed by several succeeding popes, who have added many new rights and privileges to it.

In less than half a century after its institution, the society obtained establishments in every country that adhered to the Roman Catholic church; in the year 1605, the number of *Jesuits* had increased to 10,000. In the year 1710, the order possessed 24 professed houses; 50 houses of probation; 340 residences; 612 colleges; 200 missions; 150 seminaries and boarding-schools; and consisted of 19,998 *Jesuits*.

The constitution and laws of the society were perfected by Laynez, and Acquaviva, the two generals who succeeded Loyola, men far superior to their master in abilities, and in the science of government. Several circumstances concurred to the rapid progress and extensive influence of the *Jesuits*. They were taught to consider themselves as formed for action, and bound to exert themselves continually, as soldiers, in the service of God and of the pope, his vicar on earth. And that they might have full leisure for this active service, they were totally exempted from those functions, the performance of which is the chief business of other monks. They were required to attend to all the transactions of the world; to study the dispositions of persons in high rank, and to cultivate their friendship; and by the constitution as well as genius of the order, a spirit of action and intrigue was infused into all its members. Besides, the form of government of this order was peculiar: Loyola, full of the ideas of implicit obedience, which he had derived from his military profession, appointed that the government of this order should be purely monarchical. A general, chosen for life by deputies from the several provinces, possessed power that was supreme and independent, extending to every person and to every case. He, by his sole authority, nominated provincials, rectors, and every other office employed in the government of the society, and could remove them at pleasure. In him was vested the sovereign administration of the revenues and funds of the order. Every member belonging to it was at his disposal; and by his uncontrollable mandate, he could impose upon them any task, or employ them in whatever service he pleased. To his commands they were required to yield not only outward obedience, but to resign to him the inclinations of their own wills, and the sentiments of their own understandings. There is not in the annals of mankind any example of such a perfect despotism, exercised not over monks shut up in the cells of a convent, but over men dispersed among all the nations of the earth. It is carefully provided, that the general should be perfectly informed with respect to the character and abilities of his subjects. Every novice, who offers himself a candidate for enter-

ing into the order, is obliged to manifest his confidence to the superior, or to a person appointed by him every six months; each member is likewise enjoined to observe the words and actions of the novices, and to disclose every thing of importance to the superior. The provincials and heads of the several houses are also obliged to transmit to the general, regular, frequent, and minute reports concerning the members under their inspection. These reports are digested and arranged in registers, by which the general may easily survey the state of the society in every corner of the earth; observe the qualifications of its members; and choose proper instruments for any necessary service. The number of these reports received annually by the general was 6584, which divided by 37, the number of provinces in the order gives 177 reports concerning the state of each province transmitted annually to Rome. The general also receives, by the constitution of the order, an account of the civil affairs of the country where his subjects reside; so that he is furnished with full information concerning the transaction of every private and state in the world. The *Jesuits*, from their first institution, considered the education of youth as their peculiar province; and before the expiration of the 16th century, they had obtained the chief direction of this business in every catholic country in Europe. They had also become the confessors of almost all its monarchs; they were the spiritual guides of almost every person eminent for rank or power; and they possessed the highest degree of confidence and intercession with the papal court, as the most zealous and able champions for its authority. The order, notwithstanding the vow of poverty which they contrived to elude, acquired ample possessions in every catholic country. Besides the sources of wealth common to all the regular clergy, they obtained, under a pretext of promoting the souls of their missions, and of facilitating the support of their missionaries, a special licence from the court of Rome to trade with the nations which they laboured to convert. In consequence of this they engaged in an extensive and lucrative commerce, both in the East and West Indies; they also succeeded in obtaining settlements, and accordingly acquired possessions of a large and fertile province in the southern continent of America, and trigned as sovereigns over some hundred thousand subjects.

The progress and influence of the *Jesuits* have been likewise much promoted by their mutual union for the good of the common cause; by their reputation for learning and science, in which they excel all the other orders, though M. d'Alembert says, that the order has never produced one man, whose mind was so much enlightened with found knowledge as to merit the name of a philosopher; by the severity of their discipline and regularity of their conduct and manners; by propagating a system of relaxed and pliant morality, which accommodates itself to the passions of men, justifies their vices, tolerates their imperfections, and attributes almost every action, which the most audacious or crafty politician in the world will to perpetrate. So that abbé Boullainvilliers says of them, they are a people who lengthen the creed and shorten the decalogue; by extending the jurisdiction and absolute power of the court of Rome; and by the zeal which they have manifested in combating the opinions and checking the progress of the protestants.

The end principally proposed by this order is, to gain converts to the Roman church; with which view they disperse themselves in every country and nation, and with amazing industry and address pursue the end of their institution. No difficulty so great that they cannot surmount, no danger so imminent that they will not undergo; and, as some say, no crimes so shocking that have not been perpetrated by them for the service of their cause.

Of all the *Jesuits*, who distinguished themselves by their zealous and laborious attempts to extend the limits of the church, none acquired a more shining reputation than Francis Xavier, commonly called the apostle of the Indians. He sailed for the Portuguese settlements in India in 1522, and soon diffused the knowledge and profession of the popish religion over a great part of the continent and neighbouring islands. In 1529 he laid the foundations of a considerable church in Japan against which, however, a violent persecution was commenced in 1615, and lasted several years, and terminated in the order's extirpation of Christianity, and an edict forbidding all Europeans, a few Dutch merchants excepted, to approach the Japanese dominions; and having embarked for China, he died in 1552, within sight of it. Others, after his death, and particularly Ricci, an Italian, penetrated into China, and established churches, some remains of which subsist to this day. Robert de Nobili is much celebrated by the *Jesuits* on account

account of his facts in protecting the BRACHMANI; for the method he used (see BRACHMANI). The *Jesuits* are charged by the Jansenists and Dominicans with many fraudulent practices in their attempts to propagate Christianity in China; and particularly with endeavouring to persuade the Chinese, that the doctrine of Confucius and that of the gospel were not essentially different, and that Jesus Christ had been known and worshipped in their nation many ages ago. Ricci allowed the Chinese converts to retain the profane customs and the absurd rites of their pagan ancestors; but his opinion was condemned by the Dominicans and Franciscans. This difference laid the foundation of a long and violent contest. Innocent X. in 1655, pronounced sentence in favour of the Dominicans; but, about eleven years after, Alexander VII. resumed the Chinese indulgence proposed by Ricci. Complaints were renewed by the Dominicans in 1681, and again in 1684, under the pontificate of Innocent XI. and the dispute was carried on both in Europe and China, from the year 1684, till the question was decided to the disadvantage of the *Jesuits* in the year 1704, by Clement XI. but this edict was mitigated in 1715. It is well known, that the inquisition erected by the *Jesuits* at Goa, where the body of Xavier lies interred, and is worshipped with the highest marks of devotion, and the penal laws, whose terrors they employed to freely in propagation of the gospel, contributed much more than their arguments and exhortation, which were but sparingly used, to engage the Indians to embrace Christianity.

About the beginning of the 18th century, the *Jesuits* obtained admission into the fertile province of Paraguay, in South America, where they found the inhabitants in a barbarous and savage state; they began with instructing and civilizing them; exhibiting amongst them the arts and manufactures, and accustoming them to the blessings of society, security and order. By this method they secured their esteem and confidence; and a few *Jesuits* presided over four hundred thousand Indians. However, it appears from the most credible relations, that they soon changed their views from the propagating of Christianity, to schemes of insatiable avarice and boundless ambition; and they have sent yearly to the members of their order, in Europe, immense quantities of gold, drawn from several American provinces where they have power and property, but chiefly from Paraguay, which belongs to them only; and it is evident, from later discoveries, which have proved the ruin of the *Jesuits* in Spain and Portugal, that they had established an independent empire in this province, subject to their society alone, and which, by the superior excellence of its constitution and police, could scarcely have failed to extend its dominions over all the northern continent of America. They cut off every kind of communication between the Spaniards and Portuguese in the adjacent settlements, and the Indians; injured the latter with hatred and contempt of their nation; insidiously avoided giving the Indians any knowledge of the Spaniards, or other European languages; instructed them in the art of war, formed them into bodies of cavalry and infantry, and provided them with artillery and magazines stored with all the implements of war. Such was the state of things, when, in the year 1750, the courts of Madrid and Lisbon entered into a treaty for fixing the limits of their respective dominions in South America. In the execution of the treaty, in the year 1752, the *Jesuits* demonstrated, and a war ensued between the Spaniards and Portuguese on one side, and the Indians, animated by the *Jesuits*, on the other; which was the real and original cause of the disgrace of the *Jesuits* at the court of Portugal.

The *Jesuits* have been justly charged with inculcating the most infamous and dangerous maxims with regard to morality and religion: such are the following extracted from their writings. That persons truly wicked and void of the love of God, may expect to obtain eternal life in heaven, provided that they be impressed with a fear of the divine anger, and avoid all heinous and enormous crimes through the dread of future punishment: that those persons may transgress with safety, who have a probable reason for transgressing; i. e. any plausible argument or authority in favour of the sin they intend to commit; that actions intrinsically evil, and directly contrary to the divine laws, may be innocently performed, by those who have so much power over their own minds, as to join, even idealy, a good and to this wicked action, or, in formal in their eyes, who are capable of distinguishing their intention, and that philosophical sin is of a very light and trivial nature, and does not deserve the pain of hell; by philosophical sin they mean an action contrary to right reason, which is done by a person

who is either absolutely ignorant of God, or does not think of him during the time this action is committed; that the transgressions committed by a person blinded by the seduction of lust, agitated by the impulsive and tumultuous passion, and destitute of all sense and imposition of religion, however detestable and heinous they may be in themselves, are not imputable to the transgressor before the tribunal of God; and that such transgressions may often be as involuntary as the actions of a madman; and that the person who takes an oath, enters into a contract, may, to elude the force of the one, and the obligation of the other, add to the terms of words, just express them, certain mental reservations, and tacit reservations. Some of these maxims were condemned by a public edict of pope Alexander VII. in 1659; and that relating to philosophical sin was of the same date in 1669, under the pontificate of Alexander VIII. Neither of these bulls are to be found in the *Historiam Pacificam* but they are indubitably ascribed by the Jansenists and Dominicans.

The college of the *Jesuits* was humorously and learnedly attacked by the famous Pascal, in his work entitled, *Les Provinciales, ou Lettres écrites par Louis de Montfort, à un Provincial de ses Amis et aux *Jesuits*, sur la Morale et la Politique de ces jésuites*. The *Jesuits*, however, obtained a sentence against the *Provinciales*, by which they were condemned to be burnt publicly at Paris. Another excellent book, by Perault, published at Mons, in 3 volumes 8vo. in the year 1702, entitled, *La Morale des *Jesuits*, extrait fidèlement de leurs Livres, imprimés avec la permission et l'approbation des Supérieurs de leur Compagnie, par un docteur de Sorbonne*, was burnt at Paris, in the year 1670, at the request of the *Jesuits*. The famous Arnauld, with some of his Jansenist brethren, have undertaken to prove, that the *Jesuits* reduced their pernicious maxims to practice, in a celebrated work, entitled, *La Morale Pratique des *Jesuits**, consisting of 8 volumes 8vo. the second edition of which was published at Amsterdam, in the year 1742. For an account of the controversy between the *Jesuits* and Jansenists, see JANSENISTS.

The *Jesuits* have no particular habits; but change and accommodate it to times and occasions. The order consists of five different classes; *professed fathers*, *spiritual coadjutors*, *approved scholars*, *lay brothers*, called also *temporal coadjutors*, and *novices*. Some writers make only three classes, viz. the *professed members*, the *scholars*, and the *novices*. Some add a sixth class, under the title of *aspirants*, which they say is numerous, and is incorporated with the other classes, and disguised under different sorts of apparel.

The *professed fathers*, which make the body of the company, take the three solemn vows of religion publicly, and to these add a special vow of obedience to the head of the church, as to what regards missions among idolaters, heretics, &c.—The *spiritual coadjutors* also make public vows of chastity, poverty, and obedience; but omit the fourth relating to missions.—*Approved scholars* are those, who, after two years novitiate, have been admitted, and have made three vows of religion; not solemn, indeed, but yet declared. These are in the way to become *professed*, or *spiritual coadjutors*, according as the general thinks fit. These degrees, especially that of *professed*, are never conferred till after two years novitiate, and seven years study, seven of regency, a third year of novitiate, and thirty-three years of age: the age at which our Saviour is supposed to have been crucified. The vows of the scholars are absolute on their side, but on y conditional on the side of the order; the general having it in his power to dispense with them.

The order is divided into *provinces*, the assistance into *provinciars*, and the provinces into *houses*. It is governed by a general, who is perpetual and absolute. He resides at Rome, and is elected by a general congregation of the order. He has with him five persons, who are, at times, his ministers. They are called *efficients*, and bear the name of the kingdom or country to which they belong, and by which they are appointed; viz. of Italy, France, Spain, Germany, and Portugal. To them belongs the care of preparing the masters of their respective assistance, and of putting them in a method to cultivate their diocese.

Each province has four kinds of *houses*, viz. *professed houses*, which can have no lands belonging to them; *colleges*, where the sciences are taught; *seminaries*, where are a number of workmen employed in such offices as have any immediate relation to preaching, catechizing, missions, &c. and houses of *novices*. Among the *colleges* there are some called *seminary colleges*, and others *seminary houses*. These last are set apart for the young *Jesuits*

to go through their courses of philosophy and theology in; the others are for strangers.

Each province is governed by a *provincialis*, and each house by a *superior*, who is called *rector* in the colleges, and a *superior* in the other houses. Ignatius regulated the discipline of these houses, and especially of the colleges, by what he had observed in the Sorbonne, while he studied at Paris.

The professed of this order renounce, by a solemn vow, all preferment, and especially ppeity; and cannot receive any, unless enjoined thereto by the pope, under pain of sin. This the pope sometimes does, inasmuch that they have had eight cardinals of their order.

The reader will find, in the preceding part of this article, a brief but comprehensive account of the *Jesuits*, as to their origin and influence, and the chief causes on which their influence depended, and the nature of their constitution it remains to direct his views to their decline and actual suppression, in some parts of Europe, where their credit, power, and opulence had at one time arrived to a prodigious height. In France, the assassination of Henry IV. by Jean Chatelet, one of their scholars, and the writings of the *Jesuit* Guignard, in favour of regicide, induced several of the parliaments of the provinces to expel them, as a detestable and diabolical society, the corruptors of youth, and enemies to the king and state. But they were again favoured by Louis XIII. and Cardinal Richelieu, and also by Louis XIV. in whose reign they obtained the revocation of the edict of Nantes against the protestants, and succeeded almost to their utmost wishes in suppressing the *JANSENISTS*, their inveterate enemies. However, at this period, their affairs seem to have taken a different turn. Father Tellier's violence in destroying the famous Port-Royal, and the universal commotion occasioned by the bull *UNIGENITUS*, raised clamours against them, which never subsided till their ruin. The refusal of the sacrament to the *Jansenists* served also to light up the flame which succeeded, and before it could be extinguished, effected the dissolution of the *Jesuits*. About this time, they also refused, as it is said, out of respect to the queen and dauphin, to undertake the spiritual guidance of La Pompadour; and whilst they offended the court by their scruples, they displeased it equally by their intrigues.

Living houses for disgracing persons in place, whose only crime was a disagreement for their society. They also offended men of letters, by their violent decimations against the *Encyclopédie*, and by their abuse of Voltaire, the author of the *Henriade*. In this situation of the *Jesuits*, the war broke out between England and France, which involved the society in that famous law-suit, which directly brought on its destruction. Having carried on a considerable commerce in the island of Martinico, and sustained some losses by the war, they wanted to compound their debts with their correspondents in Lyons and Marseilles. These correspondents, looking upon the society in general to be answerable for their brethren in Martinico, addressed themselves to a certain *Jesuit* in France, demanding justice. This good father, and the *Jesuits* in general, demurred, and stood trial before the grand-chamber of the Parliament of Paris, where they were said to not only sentenced to pay the immense sum in litigation, but interdicted for the future all manner of commerce. This sentence led into an examination of their constitution by their own books; which appeared to be contrary to the laws of the kingdom, the obedience due to the king, the safety of his person, and the peace of the state. Besides the *Jesuits* were grown rich, insolent, and imperious; and though they professed to have renounced the world, they were found to be tutors, courtiers, merchants, politicians, priests, and wanted nothing less than to be governors and rulers of the earth. These were sufficient motives for opposing them: the attempt to assassinate the French king in 1759, was charged on the *Jesuits*; and the actual assassination of the king of Portugal in the following year, which induced the Portuguese minister to drive them out of the kingdom, in 1759, increased the odium against them. The parliament of Paris having taken a whole year to enquire into the nature of their intrusion, and news of the capture of Martinico in the mean while arriving, the minister, as M. d'Alembert says, in order to cause a diversion, thought on the expedient of proceeding farther against the *Jesuits*; and the principal of their college was commanded to obey the orders of parliament, and to shut up their schools on the first of April 1762. On the 16th of August following, their institution was unanimously condemned by the parliament, without any opposition on the part of the lower clergy; the society was of course dissolved; and their possessions alienated and sold: the other establishments of the kingdom following sooner or later the ex-

ample of that of Paris: say some of them acted with still greater severity, driving them out of their provinces without standing upon forms of law. In general, however, individuals were permitted to reside in France, on renouncing the society, and taking oaths of allegiance to the king. In a little while after, the king issued an edict, which abolished the society throughout all France. The parliament of Paris, on registering this new edict, ordained the *Jesuits* to reside each in his own diocese, and to prefer themselves every six months before the magistrate of the place in which they shall dwell. The same strict forbids them to come within ten leagues of Paris, and banishes them at least six leagues from Versailles, but prohibits them not from dwelling at Fontainebleau and Compiègne, where the court resides at least three months in the year. See on the subject of this article Maffei's *Ecd. Hist.* vol. iii. p. 456. &c. 457. &c. vol. iv. p. 206. &c. 322. &c. English ed. 8vo. Robertson's *Hist.* Ch. V. vol. iii. p. 61. &c. 8vo. D'Alembert's Account of the Destruction of the *Jesuits*, posthumous.

JESUIT'S BARK. See *CONTEX PERENNANS*.
False Jesuit's bark, a name sometimes given to a species of *TANZV.* See *IVA*.

JESUITISSA, in the *Romish Church*, an order of nuns which followed the rule of the Jesuits, which was suppressed by pope Urban VIII. in the year 1630.

JESUS, in *Lithology*, a name given by the people of Damirick to the fifth called by Gessler the blue cloud, or capito cereuleus. It is called also *Jeser*, *Jeser*, and *Jeser*.

JESUS, Father of the orators of. See *ORATORY*.

JEL, *Jagat*, in *Natural History*, the name of a fossil substance, the characters of which are these: It is a solid, dry, opaque, inflammable body, found in large detached masses of a fine and regular structure, having a grain like that of wood, splitting more easily horizontally than in any other direction, very light, and moderately hard, not fusible, unless in a moderately strong heat, but readily inflammable, and burning a long time with a fine greenish white flame, and bituminous smell. Its specific gravity is 1.744.

Jel has been often confounded with the common canal coal, though a proper consideration of their distinguishing characters is sufficient to establish the difference between them.

Jel is always found in detached masses lodged in other strata; canal coal constitutes of itself whole strata. *Jel* has the grain of wood, and splits horizontally much more easily than in any other direction; canal coal has no peculiar grain, and splits with equal ease any way. *Jel* is but moderately hard, canal coal not less so than many stones; and *Jel* when set on fire flames a long time, canal coal but a little while. *Jel* is found in Italy, Germany and the East Indies, but no where so plentifully as in England; it is very common in Yorkshire, and other of the northern countries, and is found in many of our clay pits about London.

By distillation *Jel* yields first an acid liquor, then a thin and afterwards a thick black oil. By friction it becomes electrical, as AMBER does.

Jel, in medicine, is highly praised by the ancients, but the modern practice has never enquired whether justly or not. Dioscorides tells us, that it is an excellent emollient and discutient; he recommends a fumigation of it for discharges of the womb, and says that water, in which burnt *Jel* has been quenched, is a cordial. Aelius orders it to be extinguished in wine for the same purpose. It has been much used by the perfumers.

There is also a fictitious *Jel*, made of glass, in imitation of the mineral *Jel*; this is now usually drawn out into long hollow threads, which are cut and fashioned at pleasure.—It is much used in embroidery, and in the trimmings of mourning, and may be made of any colour, though it is usually black, and white; and of late is denominated *bagel*.

JET D'EAU, a French word, signifying a fountain that casts up water to any considerable height in the air. See *HYDRAULIC JET OF WATER*.
It is well known, that a *jet d'eau* will never raise water to high as its reservoir, and therefore gives less water than it is sent to the full height. Of this phenomenon, there are several causes: the first is, that the velocity of the lower particles of the *jet* is greater than the velocity of the upper; and therefore the lower water strikes that which is near above it, and as fluids move every way, by its impulse, widens and consequently thinsens the column. Another cause is, that the water at the top of the *jet* does not immediately fall off, but forms a kind of ball or head, the weight of which depresses the *jet*; if the *jet* be a little inclined, it will play higher, but be less beautiful; besides, the friction against the sides of the hole of the nozzle, or spouting pipe, will make a small *jet* rise to a less height than a larger one from the same

fame reservoir. To remedy this inconvenience, the spouting holes should be increased in proportion to the height of the spouting water, provided that they are not made too wide for the pipe of conduct. The fourth cause is the air's resistance, which is proportional to the square of the velocity, with which the water of the jets of different heights strikes it; and, therefore, the deficiency in height being in the same proportion, a jet that plays with a double velocity will have that deficiency four times at great, &c. Thus if a jet of five feet high loses one inch in height, by coming from a reservoir of five feet one inch high, a jet produced from a reservoir of ten feet four inches high, will rise but ten feet; and in this manner a table might be easily formed shewing by what height of reservoir jets of a determinate height may be produced. The following table shews in feet and decimals, of a foot, what jets will be produced by reservoirs of a determinate height.

Reservoir	Jet	Reservoir	Jet	Reservoir	Jet	Reservoir	Jet	Reservoir	Jet
4	4.00	12	10.58	20	34.62	28	49.24	36	72.48

By various experiments that have been made by Mr. Mariotte, Dr. Desaguliers, and others, it has been found, that if the reservoir be five feet high, a conduct-pipe 2 1/2 inch diameter will admit a jet in the spoutage from 2 of an inch to 2 of an inch, and so on as in the following table.

Height of Reservoir	Diameter of the Spoutage	Diameter of the Pipe of Conduct
5 Feet	1 to 2	1 1/2 inches
10	1 to 4	2 inches
15	1 to 6	2 1/2 inches
20	1 to 8	3 inches
25	1 to 10	3 1/2 inches
30	1 to 12	4 inches
40	1 to 16	4 1/2 inches
50	1 to 20	5 inches
60	1 to 24	5 1/2 inches or 6
80	1 to 32	6 1/2 inches or 7
100	1 to 40	7 or 8 inches

Here the jet is supposed to be within 100 or 150 yards of the reservoir; but if the conduct-pipe much exceeds this length, it must be of a larger diameter than what is here assigned. Thus for jets from 1 of an inch to those of an inch and 1/2, and from reservoirs from 20 to 40 feet height, if the distance be from 150 yards to 1/2 of a mile, the diameter of the pipe should be of 6 inches; from 1 of a mile to two miles, it must be of 7 inches; and from 2 miles to 5, it must be of 8 inches diameter for the same jet.

If it be required to keep any number of jets playing, whose spoutages are given in diameter, by one common conduct-pipe, we must find the diameter of an spoutage equal to all the given ones. Thus, if there be four spoutages of 1/2 of an inch diameter each, then the square of 1 is 1, which multiplied by the number of spoutages 4, makes 4; the square root of which is 2 = 1/2 = the diameter of the spoutage equal to all the four small ones. A pipe of conduct of 10 inches diameter will supply all the jets, as being a little more than six times as great as the diameter of the one large spoutage now found. After this manner the dimensions of a conduct-pipe may be found in any other number of spoutages.

In order to make a jet play to the greatest possible height, the part of the conduct-pipe at the spoutage should not turn up at right angles, but with a gentle easy curve for the best fracture of the spoutage, see AGRICULTURE. See also FONTAINS. Desaguliers' Course of Exp. Phil. vol. II. sect. vii. annot.

JET rings, angular pieces of jet of large dimensions, found in many parts of England, and esteemed Roman anti-

quities. They are of different kinds; some being polished, others wrought, but all of them are much too large for rings. The smallest of them are three inches in diameter; yet the bore is not above an inch and a half, which makes them as much too small for the wheel, as they are too large for the fingers.

JETALIA, in Botany, the name given by some authors to the trees, which afford the gum anime of the shops.

JESTON. See FLOTATION.

JETTY-head, in the royal dock-yard, is a name usually given to that part of a wharf, which projects beyond the rest; but more particularly the front of a wharf, which forms one of the cheeks of a cut or dry dock.

JEWEL-ships, in a ship, are two small blocks, which are suspended at the extremity of the main and fore-topgallant yards, by means of an eye-bolt, driven from without to the middle of the yard-arm, parallel to its axis. The use of these blocks is to retain the upper part of the small-topping-tails beyond the sheets of the top-sails, so that each of these falls may have its full force of action, which would be diminished by the encroachment of the other over its surface.

JEWEL-office, or JEWEL-house, an office which takes care of fashioning and weighing the king's plate, and delivering it out by warrants from the lord chamberlain.

When his majesty makes any present of plate, &c. they have the charge of providing it; with some other things less material.

The principal officers are, the master of the jewel-office, whose patent fees are 450l. per ann. a yeoman, a groom, and a clerk; all in the king's gift.

There are also in this office, in the gift of the lord chamberlain, the poet-laureat, at 100l. per ann. history the king's historiographer, at 200l. per ann. the history painter, and principal painter, at 200l. per ann. the painter in enamel, and the surveyor and keeper of the pictures, at 200l. per ann. each.

The goldsmith and jeweller are employed by the master, and are usually in his gift.

JEWES, are those who profess obedience to the laws and religion of Moses. See JUDAEISTS.

By stat. 1 Ann. c. 6. 30. if Jewish parents refuse to allow their Protestant children a fitting maintenance, suitable to the fortune of the parent, the lord chancellor, on complaint, may make such order as he shall see proper.

JEW-ills, in Law, is the famous statute 25 Geo. II. cap. 25, which enabled all Jews to prefer bills of naturalization in parliament, without receiving the sacraments, as ordained by stat. 7 Jac. 1. This act was repealed by 37 Geo. II. c. 1.

JEW'S ear. See AGRICULTURE.

JEW'S FRATERNITY, in Botany. See STOKANOSIS.

JEW'S MALLOWS. See MALLOWS.

JEW'S MINE, in Natural History. See LAPID JUDAEICUS.

JEWISH economy. See ECONOMY.

JEWISH laws. See LAWS.

JEZIDES, or JERIDEANS, a term used among the Mahometans, to signify heretics.

In which sense Frædian stands opposed to Moisselman. Lennæus tells us, that the name is derived from an emir, called Jrad, who killed the two sons of Ali, Hassan and Hussein, two grandsons of Mahomet on their mother's side, and persecuted the posterity of the prophet. The Agareniens, whose emir or prince he was, looked on him as an impious and heretical person, and hence took occasion to call all whom they accounted heretics, Jezidians.

Beaulieu conjectures, that the denomination of this sect is derived from the name of Jesus; but it seems rather to be borrowed from the Persian Jaxid or Jaxim, signifying the good God, in opposition to Arimanius, the evil principles; so that the term points out this sect as the worshippers of the good or true God. After all, this name may have been derived from the city Jezid.

Some authors mention the Jezidians as a particular people, speaking a language different both from the Turkish and Persian, though somewhat akin to the last. They farther tell us, that there are two kinds of Jezidians, the one black, the other white. The white have no fire in the bottom of their shirt, but barely an open for the head to pass through; a thing that they observe with a great deal of strictness, in memory of a circle of gold and light which they say fell from heaven upon the neck of their grand chief, or chief of their sect. The black Jezidians are fugitives, or religious, and go arrayed in sable garments.

The Turks and Jezidians bear a strong aversion to each other; and the greatest affront one can put upon a Jezid is to call him a Jezidian. On the contrary, the Jezidians love the Christians being persuaded that Jrad, their chief, is Jesus Christ; or, rather, because some of the traditions

traditions mention, that *Jesús* made an alliance with the Christians against the Mussulmen.

They drink wine, even to excess, when they can get it, and eat swine's flesh. They never undergo circumcision, excepting when they are forced to it by the Turks. Their ignorance is surprising; they have no books. Indeed they pretend to believe in the Gospel, and in the sacred books of the Jews; but they never read either one or other of them. They make wars, and go on pilgrimage; but have no mosques, temples, nor oratories, no feasts, nor ceremonies; all their religious worship consisting in singing hymns to Jesus Christ, the Virgin, Moses, and Mahomet. When they pray, they look towards the east, in imitation of the Christians; whereas the Mussulmen turn towards the south. They believe the devil may possibly, one day, come into favour again with God; and that he is the executor of God's justice in the other world; for which reason, they make it a point of prudence not to speak ill of him, lest he should revenge himself of them.

The black *Jesides* are reputed faints; and it is forbidden to weep at their death, in order that whosoever they make rejoicings at, and yet, for the generality, they are no more than shepherds. They are not allowed to kill the animals they eat; that office belongs to the white *Jesides*. The *Jesides* go in companies like the Arabs, and are an unsettled, wandering tribe, who frequent the Gordian mountains, and the deserts of Cordillán, a province of Perú. They often change their habitations, and live in black tents made of goats hair, and encompassed with large rushes and thorns interwoven. They dispose their tents in a circle, placing their flocks in the middle. They have their wives the stated price whereof is two hundred crowns, they are better or worse. They are allowed divorce, provided it be to become faints. It is a crime among them to flatter their beauty, though ever so true. They have some customs which intimate that they sprang originally out of some sect of Christians; for instance, in their feasts one of them pinches a cup full of wine to another, bidding him take the cup of the blood of Jesus Christ; which act signifies the hand of him who pretends, it, and drinks.

IGASUR, in the *Materia Medica*, a name given by some authors to the *faba sancti Ignatii*, or Saint Ignatius's bean.

IGNATIUS, *frax*, *faba sancti Ignatii*, in the *Materia Medica*, the fruit of a plant growing in the East Indies and Philippine islands, described by Father Camilli, in the Philosophical Transactions, under the name of *caralanga*, and *caralanga*; and by Plukenet, under that of *carabotifera malabarica* *faba sancti Ignatii*, *carabotifera*. The Spaniards call it *carabotifera*. It is a dry and hard fruit, or kernel of a fruit, of the size of a large hazel nut; and is much celebrated for its medicinal virtues, being recommended in vertiges, lethargies, epilepsies, asthma, quartan agues, and worms. It is also given against distempers of the stomach, and as an alexipharmac. The dose, in substance as an emetic, is ten or twelve grains; and in smaller doses it sometimes procures a plethoric sweat: Boerhaave says that he has known intermittent fevers cured, by drinking on the approach of a paroxysm, an infusion of some grains of the seed in carduus water; and Dr. Lewis has been informed, that two grains were found to have as much effect as a full dose of bark. But it seems too hazardous for general use. See *Nux vomica*.

IGNAVUS, in *Natural History*, a name given to the animal called in English the *SLUG*.

IGNIARIUS *lapis*, in *Natural History*, a name given by some to the *pyrites*, or fire-stone, from its yielding a great quantity of sparks, when struck against steel.

IGNICOLÆ, *inhabitants of fire*. See *GAEULÆ*.

IGNIS, *aquea*, *frigidus*, a name by which Helmont, in some of his writings, calls the *ALCAHEMY*, or universal dissolvent, so much talked of by him and Paracelsus.

IGNIS Fatuus, a common mist, chiefly seen in dark nights frequenting meadows, marshes, and other moist places, and often seen in burning-grounds, and near dung-hills. It is known among the people by the appellation, *Will with a will*, and *Jack with a lantern*.

Sir Isaac Newton calls it a vapour shining without heat; and it has been supposed to be of the same nature with the light issuing from putrescent substances. Willoughby and Ray were of opinion that it is occasioned by shining insects; but all the appearances of it is contrary by Dr. Huxham, Beccaria, and others, (sufficiently) evince, that it must be an ignited vapour. The form and size of the *ignis fatuus* are very various and often variable. The late experiments on air serve to furnish a rational explication of this phenomenon, to which the igneous and superfluous have been ascribed to many stirring purposes. *Phosphoreous AIR* has been found to be the most common of all the factitious airs in nature; and to be the vital pro-

duct of the putrefaction and decomposition of vegetable substances in water; and Ignis Fatuus, in a letter to Dr. Priestley, informs him, that he fires inflammable air by the electric spark, even when the electricity is very moderate; and he supposes, that this experiment explains the inflammation of the *ignis fatuus*, provided they consist of inflammable air issuing from marshy ground by the help of the electricity of fog, and by falling stars, which are very probably thought to have an electrical origin. Priestley's *Obs. on Air*, vol. iii. Appendix, p. 382. The reader will find a particular account of various particulars relating to the *ignis fatuus* in the Phil. Trans. Abstr. vol. vii. p. 147, &c.

Dr. Shaw describes an *ignis fatuus*, which he saw in the Holy Land, that was sometimes globular, or in the form of the flame of a candle; and immediately afterwards spread itself so much as to involve the whole company in a pale insensible light, and then contract itself again, and suddenly disappear. But in less than a minute it would become visible as before; or, running along from one place to another, with a swift pre-terrestrial motion, would expand itself, at certain intervals, over more than two or three acres of the adjacent mountains. The atmosphere at this time had been thick and hazy, and the dew on their bridges was unusually clammy and unctuous.

In the same weather, he observed these luminous appearances, which, at sea, skip about the masts and yards of ships, and which the sailors call *expulsi* by a corruption of the Spanish *corpa jato*. Shaw's *Travels*, p. 262.

IGNIS gehennæ, in *Chemistry*, a name given by Paracelsus to a certain menstruum, capable of dissolving all bodies, and remaining itself unaltered by them.

Van Helmont terms to make this the same with the *ALCAHEMY*, to celebrate in his writings, and to ardently sought after by all the chemists since his time.

IGNIS judææ. See *JUDÆUM DRI*, and *ORDEAL*.

IGNISPICIUM, among the *Romans*, a species of divination taken from the fire used in furnaces. See *PYROMANCY*.

IGNITION, in *Chemistry*, the application of fire to metals, till such time as they become red-hot, without melting. This happens in gold and silver; but especially in iron: but lead and tin are too soft and fusible to bear ignition.

IGNORAMUS, *q. d. Nos non scimus*; in *Law*, a word used by the grand jury, impeached on the inquisition of causes criminal, and written upon the bill, when they disbelieve their evidence, as defective, or too weak to make good the presentment.

The effect of which is, that all further enquiry upon that party for that fault is thereby stopped, and he is delivered without further answer. See *HILLA VERA*.

IGNORANCE, the privation, or want, of knowledge. *Ignorance*, according to Mr. Locke, is chiefly owing to three causes: want of ideas; want of a disconcertable connection between the ideas we have; and want of tracing and examining our ideas. See *IDEA*.

These are some things we are ignorant of, for want of ideas; all the simple ideas we have are confined to the observation of our senses, and the operation of our own minds, which we are conscious of in ourselves. What other ideas it is possible other creatures may have, by the assistance of other senses or faculties, more or perfect than we have, or different from ours, is not for us to determine: but to say there are no such, because we conceive nothing of them, is no better an argument, than if a blind man should be positive there was no such thing as light and colour, because he had no manner of idea of any such thing.—What faculties, therefore, other species of creatures have, to penetrate into the nature and inmost constitutions of things, we know not: this we know, and certainly find, that we want other views of them, besides those we have, to make discoveries of them more perfect. The intellectual and sensible world are in this perfectly alike; that the parts which we see of either of them, hold no proportion with that we see not; and whatsoever we can reach with our eyes, or our thoughts, of either of them, is but a point, almost nothing, in comparison of the rest. Again, the want of ideas, which we yet seem capable of, is another great obstacle in our way, and keeps us in ignorance of things, which we conceive capable of being known. Bulk, figure, and motion, we have ideas of; yet, not knowing what is the particular bulk, motion, and figure, of the greatest part of the bodies of the universe, we are ignorant of the several powers, energies, and ways of operation, whereby the effects we daily see are produced. These are hid from us in some things, by being too remote; and in others by being too minute.

This, at first sight, shows us how disproportionate our knowledge is to the whole extent, even of material beings; to which if we add the consideration of that infinite number of spirits that may be, and probably are,

which are yet more remote from our knowledge, and whereof we have no cognizance at all: we shall find this cause of ignorance consists from us, in an imperceptible obscurity, about the whole intellectual world; a greater, certainly a more beautiful world, than the material: for, shewing some very few ideas of spirits, which we get from our own mind by reflection, and from thence the bulk we can collect of the Father of all spirits, the souls of them, and us, and all things: we have no certain information to much as of the existence of other spirits, but by revelation: much less have we distinct ideas of their different natures, states, powers, and several constitutions, wherein they agree or differ one from another, and from us: and therefore, in what concerns their different species and properties, we are under an absolute ignorance.

Another cause of ignorance is, the want of discoverable connexion between those ideas we have; where we want that, we are utterly incapable of universal and certain knowledge; and are, as in the former case, left only to observation and experiment. Thus the mechanical affections of bodies having no affinity at all with the ideas they produce in us, we can have no distinct knowledge of such operations beyond our experience; and can transfer no otherwise about them, than as the effects of experiments of an infinitely wide extent, which perfectly furnish our comprehension. The operation of our minds upon our bodies is as unconceivable: how any thought should produce a motion in body, is as remote from the nature of our ideas, as how any body should produce any thought in the mind. That it is so, if experience did not convince us, the consideration of the things themselves would never be able, in the least, to discover in us. In some of our ideas there are certain relations, resemblances, and connexions, so visibly included in the nature of the ideas themselves, that we cannot conceive them separable from them by any power whatsoever: in this only we are capable of certain and universal knowledge. Thus the idea of a right-lined triangle necessarily carries with it an equality of its angles to two right ones; but the coherence and continuity of the parts of matter, the production of sensation in us, of colours and sounds, &c. by impulse and motion, being such wherein we can discover no natural connexion with any ideas we have, we cannot but ascribe them to the arbitrary will and good pleasure of the wise architect. The things that we observe constantly to proceed regularly, we may conclude do not by a law set them; though by a law we know not, whereby though causes work steadily, and effects constantly flow from them, yet their connexions and dependences being not discoverable in our ideas, we can have but an experimental knowledge of them. Several effects come every day within the notice of our senses, of which we have far less sensitive knowledge; but the causes, manner, and certainty of their production, we must, for the foregoing reasons, be content to be ignorant of. In these we can go no farther than particular experience informs us of matter of fact; and, by analogy, we guess what effects the like bodies are, upon other trials, likely to produce. But as to perfect science of natural bodies (not to mention spiritual beings), we are so far from being capable of any such thing, that it may be reckoned lost labour to seek after it.

The third cause of ignorance is, our want of tracing those ideas we have, or may have; and finding out those intermedial ideas, which may show us what habits of agreement or disagreement they may have one with another; and thus many are ignorant of mathematical truths for want of application in inquiring, examining, and by due ways comparing, those ideas.

IGNORANCE, in *Law*, is a want of knowledge of the laws; which will not excuse a person from suffering the penalty annexed to the breach of them; because every one is obliged, at his peril, to know the laws of the land.

IGUANA, in *Zoology*, the name of a species of lizard, very frequent in the West-Indies. It is an amphibious animal, of the lizard-shape, and in colour partly brown and partly grey, in some of the animals; and is colored of a beautiful green, variegated with black and white spots. From its neck to the extremity of its tail, it has a continued series of flat-pointed and serrated scales, of a fine green colour. These are largest at the neck.

JIB, in a *Ship*, is the fore-mast-fall of it, being a large stay-fall extended from the outer end of the bowsprit, prolonged by the jib-boom, towards the fore-top-mast-head.

Jib-Ram is a boom run out from the extremity of the bowsprit, parallel to its length, and serving to extend the bottom of the jib, and the stay of the fore-top-gallant-mast. It is attached to the bow-sprit by means of two

large boom-irons, or by one boom-iron, a cap on the outer end of the bowsprit; or by the cap without, and a strong lifting within.

JIBING. See *CRANING*.

JIG, in *Music*, &c. See *GIG*.

JIGGER, in *Sea Language*, is a machine consisting of a piece of rope about five feet long, with a block at one end, and a sheave at the other; and used to hold on the cable, when it is heaved into the ship by the revolution of the windlass. See *HOLDING* &c.

JOURN-TABLE is a light small table, consisting of a dozen or single block, used on various occasions by frigate.

JUVA, in *Zoology*, the name of an American serpent, of the order-kind, called also *carolinensis*. It is an amphibious creature, of the size of a middle-sized snake. Its head is round, and like a cat's; but its nose is not pointed; its eyes are black; its ears rounded, and placed very low in the oyster; and it has a forked tongue, or whiffers composed of a few stiff hairs; the feet have all five toes, the inner one being smaller than any of the others; the hair is soft, not long, and all black, except those on the head, which are brown, and some which compute a yellowish spot under the throat. Its nose is much like that of a young puppy. It feeds on fish, and other animals. Ray.

KENILD Stream, one of the four famous wells, that the Romans made in England. See *WATERING-SPRINGS*.

KATHERA Rock, in *Peru*. See *CLUTIA*.

KLEX, in *History*. See *HOLLY*.

ILIAC PASSION, a violent and dangerous kind of colic; called also *colica, miferiosa, miferica, and dysenteria*. It takes its name from the intestine *iliac*, on account of its being usually affected in this distemper; or, perhaps, from the Greek verb *ilao*, to twist, or to twist whence also it is the Latin call it *volvulus*.

This disorder is a violent pain in the small intestines, in which the peristaltic motion of the bowels is inverted, and all their contents are thrown up by vomit.

Medical writers distinguish this into three kinds: 1. The convulsive. 2. The hernic. And, 3dly, the obstruative.

In the convulsive kind, the function of the intestines in regard to one another is altered, and very frequently has a remarkable duplicature. In the hernic kind, the intestines, distended with feces and with flatulencies, are received into the scrotum, or some other part, so as not easily to be reduced into their natural places. And in the obstruative, there is no other cause but a violent cohesiveness.

The *miseriosa* differs from the ordinary kind of colic, in degree, as all the symptoms are much more violent in this case; and in its situation, as the iliac and small guts are affected in this, and in the other colics usually the larger; and it is always a much more dangerous case than an ordinary colic.

Signs of it. These are extremely sharp and violent pains across the navel, a remarkable anxiety of mind, with frequent eruptions and heartburn, and great internal heat; a violent obstruction in the bowels, in which efforts have very little or no effect; and as the distension increases, a vomiting, which, as it continues, at length brings up the stools by the rectum, with violent pains, and frequent faintings; after this, unless the medicines take place, there comes on an inflammation of the ilium, and thence a suppuration and mortification, on which the pains instantly go off, and the patient falls into cold sweats, and dies in a very little time after. It is a very rare case, and though many colics are called by this name, yet in reality it is rarely met with. People, however, of all ages and sexes, are equally subject to it from the following causes.

Causes of it. These are either a convulsion of the intestines, with an immediate inflammation, or a tumor in the parts of the intestine contained in the hernial sack, and the use of violent and powerful astringent medicines bringing on such a cohesiveness as never happens naturally. Violent convulsions of the body in leaping, riding, or running, have been known sometimes to bring on the disease, as also violent sneezing and coughing, and the carrying of too great weights; as also colds, and such as have been induced by frosts, and violent and fermenting liquors. Sometimes also it has been evidently owing to worms killed in the bowels, and not voided by stool.

Prognosis of it. This is a very terrible disease, both in regard to the danger that attends it, and to the pain. In cases where its origin is from a distension and convulsion of the intestines, there is very little hope of recovery; and when it arises from a hernia, it is very often fatal also, especially when attended with an inflammation and picrosis. Its mildest state is when it arises only from indurated stools, and an obstinate cohesiveness;

constituted, this is usually cured, if proper assistance be given in time.

Method of cure. When a convulsion of the intestines is the cause, the whole effort is to be used to explicate them; but this is a thing more easily conceived in the mind than effected: to this purpose some recommend the swallowing of a mackerel butter, others a globe of agimony, and others a pound of quicksilver, taking before hand a spoonful or two of oil of sweet almonds; and ordering motion by walking or riding afterwards; others advise the introducing the nose of a pair of bellows into the orifice of the rectum, and blowing up into the intestines; but as that gut is usually so contracted in this case, as to refuse to admit the pipe of a sphygmometer, there is no great hope of succeeding in the latter attempt; and others finally advise the throwing in the fume of tobacco. Some ancient authors have recommended to make an opening into the cavity of the abdomen, in order to discover and disengage the strangulated intestine; and some few histories are recorded which seem to favour this practice. But the difficulty of ascertaining with precision the true cause of the disease renders it hazardous and painful an operation as CAUTERIZATION hardly ever advisable. The diffusion of the inflammation is feared less necessary than the other; this is to be done by powders of niter, cinnamon, and crabs eyes, taken four times a day, and by rubbing the abdomen with camphorated spirit of wine, in which saffron has been infused; bags of carminative ingredients, with camphor, may also be applied to the abdomen with good effect; and, finally, if there be a plethoric habit, bleeding is a very necessary operation.

In cases where this is occasioned by a hernia, the first thing to be done is the reducing the intestine into its proper place. To this purpose the patient must lie upon his back, and emollient and carminative fomentations must be applied to the part, shade of decoctions of marsh-mallows, camomile flowers, and the seeds of anise, fennel, and fennel-seeds, boiled in milk; and, when there is no inflammation, fomentations of this kind may be applied in the manner of cataplasms, by wetting a sponge with them, and applying it to the part. An inflammation is carefully to be guarded against, by stimulant medicines, and by gentle diaphoretics; and as soon as the gut is replaced, clysters must be given to bring on again a laxity of the bowels. See *HERNIA incarcinata*.

When the case only arises from an induration of the facts, there are first to be given internally nitrous and carminative medicines, to prevent or take off an inflammation, and at the same time clysters are to be given, with the emollient decoctions, and a little niter and camphor, with some oil; and if it be necessary for a yet farther stimulus, some Venice soap may be added; acrid suppositories are to be introduced into the rectum, and the soap plaster to be applied to the abdomen, or else spirit of wine camphorated is to be rubbed in: bags with carminative ingredients may also be applied warm, and where the state is plethoric, bleeding is necessary.

Bleeding is, indeed, of essential importance; it should be performed as soon as the symptoms of inflammation appear, and be repeated according to the strength of the patient and violence of the disease. A blistering plaster should likewise be applied over the part most affected with pain. Fomentations and clysters must by no means be omitted. The patient's feet and legs should be frequently bathed in warm water, and cloths dipped in it applied to his belly. The clysters may be made of barley water, or thin gruel with salt, and softened with sweet oil or fresh butter; and they may be administered every two or three hours or oftener, if the patient continues constipated.

These are the general methods, and usually one or other of them takes effect in the milder cases. But it is to be observed, that honey, though ordered by some, is never to be put into these clysters, for where there is an inflammation, it promotes suppurations. The patient is to be kept quiet and warm during the course of his disease, and the diet is to be very sparing, though the drinking warm liquors, such as clear whey, or barley-water, is to be indulged.

If the disease does not yield to clysters and fomentations, recourse must be had to pretty strong purgatives, which should be joined with opiates. Two ounces of the bitter purging salts may be dissolved in a pint of warm water or cold gruel, and a tea-spoon full of it taken every half hour till it operates. At the same time, fifteen, twenty or twenty-five drops of laudanum may be given in a glass of peppermint or single cinnamon water, to suppress the irritation and prevent the vomiting, &c. The patient's drink may be sharpened with cream of tartar, juice of lemon, or vinegar. When no liquid will stay on the stomach, purging pills made of powdered jalap

and viriolated tartar, of each half a dram, one grain of opium, and a sufficient quantity of Castile soap, these may be taken at one dose, and if they do not produce effect in a few hours, the dose may be repeated. If these methods fail to procure a stool, the patient may be immersed in warm water up to the breast, and continue in the water as long as he can bear it without shivering; and if necessary, this bathing should be several times repeated. In desperate cases, recourse is had to quicksilver, which is given to the quantity of several ounces, or even of a pound. Those who would avoid this disease, must take care never to be long without a stool: they should always be aware of eating too freely of sour or unripe fruit, or baked meats, or drinking hard windy liquors. The disorder has proceeded sometimes from wet cloaths and wet feet. Junker's Comp. Med. p. 317, &c. Buchan, Dom. Med. p. 317. See 1776.

Dr. Hunter takes notice of a disease to which children are more particularly subject, because their mesentery, having scarce any fat upon it, easily slips with the gut; and of this he observes there are two kinds; the first is when a part of the gut is received into the part next above it; the other is when a part of the gut is received into the part of the gut next below it. See an account of a particular case of this disorder in London Med. Obs. vol. iv. art. 17. p. 223.

ILIAC vessels, are the arteries and veins. The *iliac arteries* are formed by the bifurcation of the aorta, at the last vertebra of the loins. They descend about three fingers breadth from their origin; and then each *iliac trunk* is divided into two secondary arteries, one external, the other internal. The external artery runs down on the *iliac muscle* to the ligamentum Palfopi, under which it goes out of the abdomen. In this course, it sends off only a few small arteries to the peritoneum and other adjacent parts; but as it passes out of the abdomen it divides into two considerable branches, the one or internal branch called the *hypogastric artery*, and the other or external called the *circumflexa*. The internal *iliac or hypogastric artery*, having run a little more than a finger's breadth inward and backward, bends by small degrees obliquely forward and toward the outside; and afterwards, controlling in its dimensions, ends in the *umbilical artery*.

The *iliac veins* are formed by the bifurcation of the vena cava, about the last vertebra of the loins. Precisely after their leaving the vena cava, they each divide into two principal branches; one called *iliac interna* or *interna*, or simply *iliac*; the other *interna* or *pubica*, called also *hypogastria*. The external vein seems to be the continuation of the trunk, and the *hypogastria* only a branch. They pursue the same course as the arteries of the same name. Winslow.

ILIACUS externus, a muscle of the thigh. See *PERITORMIS*.

ILIACUS internus, a muscle of the thigh, which arises fleshy from the internal concave part of the os ilium; and, in its descent over the inferior part of it, joins with the psoas magnus, and is inserted with it, into the termination of the pectineus.

This, with the psoas magnus, moves the thigh forward in walking.

ILIAD, *Ilia*, the name of an ancient epic poem, the first, and greatest, of those composed by Homer.

The word is derived from the Greek *Ilia*, of *Ilion*, *Ilium*, Troy, a famous city of Asia, which the Greeks besieged for the space of ten years, and at last destroyed, on account of the rape of Helena, which makes the subject of the work.

The poet's design in the *Iliad* was, to show the Greeks, who were divided into several little states, how much it was their interest to preserve a harmony and good understanding among them. In order to which, he first before their eyes the calamities that befel their ancestors from the wrath of Achilles, and his misunderstanding with Agamemnon; and the advantage that afterwards accrued to them from their union. See *FABRI*.

The *Iliad* is divided into twenty-four books, which are marked with the letters of the alphabet.—Pliny gives us an account of an *Iliad* written on a very slender a paper, that the whole might be contained in a nut-shell.

For the conduct of the *Iliad*, see father Bossey, Malm Dacier, and M. De la Motte.

The critics maintain the *Iliad* to be the first, and yet the best, poem that ever appeared in the world: Aristotle's *Poetics* is almost taken wholly from it; the philosopher had nothing to do, but to form precepts from the poet's practice.—Some authors tell us, that Homer invented not only poetry, but all other arts and sciences; and that there are the visible marks of a perfect knowledge in every one of them, to be seen in the *Iliad*.

The ingenious Mr. Barnes, of Cambridge, has very strenuously

niously attempted to prove Solomon to have been the author of the *Book*.
The English translation of the *Book* by Mr. Pope, is well known.

ILLISIDES, in *Mythology*, a surname of the Muses, from the river *Ilissus* in Attica, the waters of which were reckoned *lustral*.

ILLITHYA, derived from *Illithia*, is *Spina* from, in *Mythology*, the daughter of Juno, and sister of Hebe, who presided over abortions. This goddess had a temple at Rome, in which were registered the birth and death of every citizen: a custom established by Servius Tullius.

ILLVLJHU, in *Natural History*, a name given by the inhabitants of the Philippine Islands to a very remarkable species of bird, common in that country. It is called by some writers *corvus parvus minuscule*, the small mountain quail, and it is indeed a quail in all the characters; but it is very beautifully variegated in its colour, and is smaller than a sparrow. It lives in hilly places, and is a very well tailed bird. See *QUAIL*.

ILLUM, in *Medicine*. See *ILLUMINATE*.

ILLUM, in *Medicine*, was so called by the ancients, because it supports the parts they called the *lunae*. It is the largest of the three bones of the pelvis. It is flat, very broad, unequally convex, and concave; partly round, and partly of an irregular square figure. It is divided commodiously enough into the crista, basis, anterior and posterior edge; and two sides, one external, the other internal. The crista is the upper part, and is a pretty thick arched border, the circumference of it is

little more than a quadrant of a circle; the anterior and middle part is convex outward, the posterior part a little convex inward. Asymmetry, for the sake of regularity in their dispositions, distinguishes it in two halves and a middle space or interval between them. It is originally an epiphysis, of which we sometimes see plain marks in a very advanced age. The posterior portion of the crista, which is convex inward, is much thicker than the anterior; and, for that reason, may be called the tuberculum of the crista. The whole crista appears to be covered over with a cartilage; but this in reality is no more than the dried tendinous expansion of the muscles. The anterior edge of this bone has two eminences or tubercles, called the anterior spines, one superior, the other inferior; and likewise two notches, one between the spines, the other below the inferior spine.

The posterior edge is shorter and thicker than the anterior; it terminates likewise in two eminences or spines, between which there is a considerable notch. The basis or inferior part of the bone, is the thickest and narrowest of all; it forms externally a portion of the acetabulum, and posteriorly almost all the iliaciac sinus. The outside is convex on the fore-part, and concave on the back-part; we observe on it the remains of a long semicircular line, which reaches from the upper anterior spine to the great iliaciac sinus, being a muscular mark; and above, and behind this impression, there are several other muscular marks. A little above the edge of the acetabulum, we see likewise many inequalities, which surround part of the edge in a semicircular form, being a collection of muscular and ligamentary marks. The inside of this bone is unequally convex, and has several inequalities toward the back part. The chief of these is that large cartilaginous surface of the figure of a great S, or a bird's head; which answers to the lateral surface of the os sacrum, with which it is connected by a cartilaginous symphysis. The other inequalities are much of the same kind with those of the lateral part of the os sacrum, from which they form several rough and irregular cavities. From the upper part of the cartilaginous surface or symphysis, all the way to the oblique eminence, runs a prominent line, which bounds the convexity of the inside of this bone, and distinguishes the margin of the pelvis from the bottom. Winslow. See *OS* and *OS ILLUMINATUM*.

ILLECERUM, in *Mountain Geography*. See *WHITLOW*.

ILLEGITIMATE, *North*, or *illegitimate*. See *DELIVERY*, and *ABORTION*.

ILLEVABLE, in *Law*, a debt or duty which cannot, or ought not, to be levied.

The word *will* is usually set on a debt, or due, that is *illevable*.

ILICUM, *flavus acutifolius*, in *Botany*, a genus of the *Andromeda* class: the characters of which are that the calyx is four-leaved and deciduous; the petals are eight; the noctaria are eight and subulate; the stamina are sixteen, with broad anthers; the fruit is an ovate, compressed, monomerous capsule. This tree is a native of Japan, China, and other parts of the East, as well as of both the Floridas in America. M. Geoff.

frey says, that it is esteemed in China and all over the East, for curing any bad taste in the mouth, as a preservative against the effects of bad air, and also for the stone and gravel. The Indians make a vinous liquor, by steeping the fruit in water and fermenting the infusion. The Dutch, as well as the natives in the East Indies, mix this fruit with their tea, and herb tea. The Chinese and Japanese esteem it a sacred tree, and they offer it to their idols, and burn the bark of it, as a perfume, on their altars: and lay the branches on the graves of the dead, as an offering to the phos of their pious departed friends. Mr. Ellis concludes, from the distinguishing characters of this genus, that it should be ranked in the *Andromeda* class. Phil. Trans. vol. lx. p. 524.

ILLITERATURE, in *Law*, if an illiterate man be to seal a deed, he is not bound to do it, if none be present to read it, if required; and reading a deed false will make it void. 2 Rep. 3. 11. A man may plead *non est factum* to a deed read false; as where a release of an annuity was read to an illiterate person, as a release for the arrears only, &c. agreed to be released. Moore, 143. If there is a time limited for a person to seal a writing; in such case illiterate shall be no excuse; because he might provide a skillful man to instruct him; but when he is obliged to seal it upon request, &c. there he shall have convenient time to be instructed. 2 Nelson's Abr. 926.

ILLUMINATION, in a general sense, denotes the act of a luminous body, or a body that emits light; sometimes, also, the state of an opaque body that receives it.

ILLUMINATION, circular. See *CIRCLE*.

ILLUMINATIVE, *lunar month*. See *MONTH*.

ILLUMINATED, *ILLUMINATI*, a Church term, anciently applied to such persons as had received baptism.

This name was occasioned by a ceremony in the baptism of adults, which consisted in putting a lighted taper in the hand of the person baptized, as a symbol of the faith and grace he had received in the sacrament.

ILLUMINATED, *ILLUMINATI*, is also the name of a sect of heretics, who sprung up in Spain about the year 1475, and were called by the Spaniards, *Alumbrados*. Their principal doctrines were, that, by means of a sublime manner of prayer, which they had attained to, they entered into to perfect a state; that they had no occasion for ordinances, sacraments, nor good works; and that they could give way, even to the vilest actions, without sin.

The sect of *Illuminados* was revived in France, in the year 1634, and were soon after joined by the Guerinets, or disciples of Peter Guerin, who together made but one body, called also *Illuminados*; but they were to boot purged by Louis XIII. that they were soon destroyed.

The brothers of the *Red Cross* are sometimes also called *Illuminados*. See *ROSECRUICIAN*.

ILLUSTRIOUS, *ILLUSTRIUS*, was heretofore, in the Roman empire, a title of honour peculiar to people of certain rank. It was first given to the most distinguished among the knights, who had a right to bear the clavus; afterwards, those were entitled *illustres*, who held the first rank among those called *securati*; that is the praefecti praetorii, praefecti urbis, praefecti comites, &c.

There were, however, different degrees among the *illustres*; as in Spain they had gradations of the first and second class, so in Rome they had their *illustres*, whom they called *graves*, *maiores*; and others less, called *illustres minores*.—For instance, the praefectus praetorii was a degree below the master of the offices, though they were both *illustres*.

The Novels of Valentinian distinguish as far as five kinds of *illustres*, among whom the *illustres administratores* bear the first rank.

IMAGE, *IMAGO*, in *Optics*, a natural, lively representation of an object, opposed to a smooth, well-polished surface, or mirror.

The Latin word *imago*, comes originally from the Greek *phantasia*, *imitatio*, to imitate, or mirror.

IMAGE, taken more largely, denotes the species, or appearance, of an object; whether by reflexion or refraction.

In all plane mirrors, the *image* is of the same magnitude as the object; and appears as far behind the mirror, as the object is before it.

In convex mirrors, the *image* appears less than the object; and farther distant from the centre of the convexity than from the point of reflexion.

Mr. Molyneux gives the following rule for finding the diameter of an *image*, projected in the distinct base of a convex mirror: as the distance of the object from the mirror is to the distance from the *image* to the glass; so is the diameter of the object, to the diameter of the *image*. See *LEN*, *MIRROR*, *REFLECTION*, and *REFRACTION*.

MARK is also used for the trace, or mark, which outward objects impress on the mind, by means of the organs of sense. See **IDEA**.

IMAGE also signifies an artificial representation performed by man; as in painting, sculpture, and the like.—In which sense the word is now generally used in speaking of things holy, or imagined to be so.

The noble Romans preserved the *images* of their ancestors, with a great deal of care and concern, and had them carried in procession at their funerals and triumphs: these were commonly made of wax, or wood; though sometimes of marble, or brass. They placed them in the vestibules of their houses; and they were to stay there, even if the house happened to be sold, it being accounted impious to displace them. Appian Claudius was the first who brought them into the temples, in the year of Rome 259, and he added inscriptions to them, shewing the origin of the persons represented, and their brave and virtuous achievements.

It was not, however, allowed for all, who had the *images* of their ancestors in their houses, to have them carried at their funerals; this was a thing only granted to such as had honourably discharged themselves of their offices; for those who failed in this respect, forfeited that privilege; and in case they had been guilty of any great crime, their *images* were broken to pieces.

The Jews absolutely condemn all *images*, and do not so much as suffer any statues or figures in their houses, much less in their synagogues, or places of worship.

The use and adoration of *images*, are things that have been a long time controverted in the world.

It is plain from the practice of the primitive church, recorded by the earlier fathers, that Christians, for the first three centuries after Christ, and the greater part of the fourth, neither worshipped *images* nor used them in their worship. However, the greater part of the Popish divines maintain, that the use and worship of *images* were as ancient as the Christian religion itself: to prove this, they allege a decree, said to have been made in a council held by the Apostles at Antioch, commanding the faithful, that they may not err about the object of their worship, to make the *images* of Christ and worship them. Baron ad ann. 102. But no notice is taken of this decree, till 700 years after the Apostolic times, after the disputes about *images* had commenced. The first instance that occurs in any credible author of *images* among Christians, is that, recorded by Tertullian de Pudicitia, c. 10, of certain cups, or chalices, as Bellarmine pretends, on which was represented the parable of the good shepherd carrying the lost sheep on his shoulders; but this instance only proves, that the church, at that time, did not think emblematical figures unlawful ornaments of cups or chalices. Another instance is taken from Eusebius, Hist. Eccl. lib. vii. cap. 18, who says, that in his time, there were to be seen two brass statues in the city of Panticos or Caesarea Philippi; the one of a woman on her knees, with her arms stretched out, the other of a man over against her, with his hand extended to receive her: these statues were said to be the *images* of our Saviour, and the woman whom he cured of an issue of blood. From the foot of the statue representing our Saviour, says the historian, sprung up an exotic plant, which as soon as it grew to touch the border of his garment, was said to cure all sorts of dilempens. Eusebius, however, vouches none of these things; nay, he supposes that the woman who erected this statue of our Saviour was a pagan, and ascribes it to a pagan custom. Farther, Philostorgius, Eccl. Hist. lib. vii. c. 3, expressly says, that this statue was carefully preserved by the Christians, but that they paid no kind of worship to it, because it is not lawful for Christians to worship brass or any other matter. The primitive Christians abstained from the worship of *images*, not, as the Papists pretend, from tenderness to heathen idolaters, but because they thought it unlawful in itself, to make any *images* of the Deity. Justin Mart. Apol. ii. p. 44. Clem. Alex. Strom. 5. Strom. 1. and Protr. p. 46. Aug. de Civit. Dei, lib. vii. c. 5, and lib. iv. c. 32. Id. de Fide et Symb. c. 7. Lactant. lib. ii. c. 3. Tertull. Apol. c. 12. Arnob. lib. vi. p. 262. Some of the fathers, as Tertullian, Clements Alexandrinus, and Origen, were of opinion, that, by the second commandment, the art of painting and engraving were rendered unlawful to a Christian, styling them evil and wicked art. Tert. de Idol. cap. 3. Clem. Alex. Admon. ad Gent. p. 41. Orig. contra Celsum lib. vi. p. 182. The use of *images* in churches as ornaments, was first introduced by some Christians in Spain, in the beginning of the fourth century; but the practice was condemned as a dangerous innovation, in a council held at Elbert in 305. Epiphanius, in a letter preserved by Jerome, tom. ii. ep. 6. bears strong testimony against *images*, and may be considered as one of the first Iconoclasts. The custom of admitting pictures of saints

and martyrs into the churches, for this was the first source of *image* worship, was rare in the latter end of the fourth century; but became common in the fifth: however, they were still considered only as ornaments; and even in this view, they met with very considerable opposition. In the following century the custom of thus adorning churches became almost universal, both in the East and West. Petaus expressly says, (de Incar. lib. xv. cap. 14.) that no statues were yet allowed in the churches; because they bore too near a resemblance to the idols of the gentiles. Towards the close of the fourth or beginning of the fifth century, *images*, which were introduced by way of ornament, and then used as an aid to devotion, began to be actually worshipped. However, it continued to be the doctrine of the church, in the fifth and in the beginning of the seventh century, that *images* were to be used only as helps to devotion; and not as objects of worship. The worship of them was condemned in the strongest terms by pope Gregory the Great; as appears by two letters of his written in 601. From this time to the beginning of the eighth century, there occurs no single instance of any worship given or allowed to be given to *images*, by any council or assembly of bishops whatever. But they were commonly worshipped by the monks and populace in the beginning of the eighth century; inasmuch, that in the year 726, when Leo published his famous edict, it had already spread into all the provinces subject to the empire. See the history of the opposition to them under ICONOCLASTS. See Bower's Hist. of the Popes, vol. iii. p. 202, &c. The Lutherans condemn the Calvinists for breaking the *images* in the churches of the Catholics, looking on it as a kind of sacrilege; and yet they condemn the Romanists (who are professed *image worshippers*) as idolaters: nor can these last keep pace with the Greeks, who go far beyond them in this point; which has occasioned abundance of disputes among them. See ICONOCLASTS. The Mahometans have a perfect aversion to *images*; which was what led them to destroy most of the beautiful monuments of antiquity, both sacred and profane, at Constantinople.

IMAGE, in Rhetoric, also signifies a lively description of any thing in a discourse.

Images in discourse are defined, by Longinus, to be, in general, any thoughts proper to produce expressions, and which present a kind of picture to the mind.

But, in the more limited sense, he says, *images* are such discourses as come from us, when, by a kind of enthusiasm, or an extraordinary emotion of the soul, we seem to see the things whereof we speak, and present them before the eyes of those who hear us.

Images, in rhetoric, have a very different use from what they have among the poets: the end principally proposed in poetry is, astonishment and surprise; whereas the thing chiefly aimed at in prose, is to paint things naturally, and to shew them clearly. They have this, however, in common, that they both tend to move, each in its kind.

These *images*, or *pictures*, are of vast use, to give weight, magnificence, and strength, to a discourse. They warm and animate it; and, when managed with art, according to Longinus, seem, as it were, to tame and subdue the hearer, and put him in the power of the speaker. See HYPOTYPOSIS.

IMAGINARY *res*, in Algebra. See ROOT.

IMAGINATION, a power or faculty of the soul, whereby it conceives and forms ideas of things, by means of impressions made on the fibres of the brain, by sensation. This power depends on the memory. Ideas enter into the mind by the senses; the memory retains them; and the *imagination* compounds them. Some writers have distinguished two sorts of *imagination*; the one, which consists in retaining the simple impression of objects, is called the *passive imagination*; the other arranges the images that are received, and combines them in a thousand ways, and is called the *active imagination*. The organs of our senses are composed of fibrillae, or little fibres, which, at one end, terminate in the outward parts of the body and skin, and at the other in the middle of the brain. These fibres may be moved two ways: either beginning at that end which terminates in the brain, or at that which terminates without. Now the agitation of these fibres cannot be communicated to the brain, but the soul will be effected, and perceive something. If then the agitation begins where objects made their first impression, viz. on the external surface of the fibres of our nerves, and is communicated thence to the brain; the soul, in that case, judges that what she perceives is without; that is, she perceives an external object as present: but if only the anterior fibres be moved by the course of the animal spirits, or in some other manner,

the soul then imagines, and judges, that what she perceives is not without, but within the brain; that is, she perceives an object as absent, and herein lies the difference between sensation and imagination.

The faculty of *imagination*, or *imagination*, only consists, according to the doctrine of Malbranche, in the power which the soul has of forming images of objects, by producing a change in the fibres of that part of the brain, which may be called the principal part, because it corresponds to all the parts of our body, and is the place where the soul (if it may be so said) immediately reflects; matters not which that part is, nor whether the opinion of Willis be true, who places the common sense in the two bodies, called *corpus striatum*, and the *imagination* in the *corpus callosum*; or that of Fernelius, who places sensation in the pia mater that encompasses the substance of the brain; or that of Descartes, who places it in the pineal gland: it suffices that there is some such part.

Since then the *imagination* only consists in a power which the soul has of forming images of objects, by impressing them on the fibres of the brain, it follows that the larger and more distinct the vestigia or tracks of the animal spirits, which are the fibres or strokes, as it were, of those images, are; the more strongly and distinctly the soul *imagines* those objects.—Now as the breadth, depth, and cleanness of the strokes of a sculpture depend on the force wherewith the graver acts, and the obedience which the copper yields, to the depth and cleanness of the tracks of the *imagination* depend on the force of the animal spirits, and the constitution of the fibres of the brain; and it is that variety which is found in those two things, to which we owe almost all that vast difference which we observe in people's minds.—On the one side are abundance and fecundity, briskness and flowery, largeness and smallness, of the animal spirits; and on the other hand, delicacy or grossness, humidity or dryness, fineness or flexibility of the fibres of the brain; and lastly, a particular relation which the animal spirits may have with those fibres: from the various combinations of which things, will result a sufficiently great variety, to account for all the different characters, which appear in the minds of men; and from the same principle flows that difference which is observed in the same person's mind, at different times, and under different circumstances, as in childhood, manhood and old age, in sickness, health, &c.

It may here be observed, that the fibres of the brain are more agitated by the impression of objects, than by the course of the animal spirits; and for this reason the soul is more affected with objects, which it perceives by sensation, and which it looks on as present, and capable of giving it pleasure or pain, than by those perceived by *imagination*, which it judges to be distant.—And yet it sometimes happens, that in persons whose animal spirits are extremely agitated by falling, waking, drinking, a fever, or some violent passion, their spirits move the inward fibres of the brain as forcibly as inward objects do; so that those persons perceive things by sensation, which they should only perceive by *imagination*; for *imagination* and *sensation* only differ from each other, as the greater from the less. See Malbranche, Recher. de la Verité, lib. ii. See MADNESS, DEPRESSION, PHRENSY, MELANCHOLY, &c.

Imagination or fancy, says the ingenious Mr. Harris, though as to its origin it may be subsequent to sense, yet is truly prior to it in dignity and use. It is this which retains the fleeting forms of things, when things themselves are gone, and all sensation is at an end. The difference between sense and *imagination* appears from hence, that we have an *imagination* of things that are gone and extinct, which cannot be made the objects of sensation. We have an easy command over the objects of our *imagination*; whereas our sensations are necessary, when their objects are present. *Imagination* is also distinguished from memory, as the former views some object of sensation repeated within us, without thinking of its rise, or referring it to any sensible object, whereas memory views each object, referring it at the same time to that sensible object, which in those past was its cause and original, and recollection is the road which leads to memory, through a series of ideas, however connected, whether rationally or casually. Besides, *imagination* may exhibit, after a manner, things that are to come; but memory is confined in the strictest manner to the past. Hermes, p. 354, &c. ed. 2d.

The histories of monstrous births, where the imperfection or deformity is ascribed to the *imagination* of the mother, are numberless; and indeed so well authenticated, that an advocate for the power of *imagination* in pregnant women, will triumphantly exclaim, that facts are stubborn things; and that all reasoning is sophistry, when opposed to them. But the answer to this kind of argument is, that experience shews it to be difficult to ascertain a fact; and that when we coolly and carefully examine the truth of

reputed facts, they are often discovered to have been advanced through haughtiness and credulity, and to have been perpetuated through ignorance and servility.

The productions of nature, in the several classes both of living and inanimate things, are not all equally perfect: we see in birds, beasts and plants, every now and then, an irregular or preternatural formation; but where the accident happens in the human species, an opinion has been adopted, that a fright, or some other affection of the mother, in the course of her pregnancy, has wrought the change. The advocates for this opinion, if they mean any thing, must mean, that at the instant the mother received the impression, the child was of the natural form, but that by the power of her *imagination* the structure of the parts was that moment altered, and assumed the appearance, either gradually or suddenly, with which the child was born. They must conceive that the infant who is born with a large discolouration on any part of its skin, had, before the discolouration took place, a fair skin; that the child who is born with six toes, had originally but five; and again, that the child who is born with one leg or one arm, had originally two, and so of every other preternatural appearance, whether it be an increase or decrease of the parts of the body.

By exposing the absurdity of one example, it will appear that all the other wonderful stories of the same kind are equally absurd. It has been alleged, for instance, that a lady advanced five or six months in her pregnancy, has been so terrified by a beggar thrusting the flumps of an amputated arm into the coach, that the child of which she was afterwards delivered, was born with a flump of arm resembling that of the beggar. Here let us pause a while, and consider what an operation must be performed to work this effect. A child at the term of five or six months, is of considerable bulk, and the arm itself not small. This arm then must drop off by the power of *imagination*: there must be no blood lost to endanger the life of the child; and the wound must be healed before the birth. The mere stating of this position exposes its ridiculousness.

But admitting that a limb could drop off by the force of fancy, it must still remain with the mother until the delivery; and the bones at least would not putrify and waste away, though the flesh would. But it never was pretended that in cases of this nature, any part of the deficient limb was found by the midwife; and what is worth observing, that the flumps of all such imperfect limbs, have a smooth skin, which plainly indicates they were from their first formation of the same figure; for had there been a wound, there would have been a scar, and scars are very distinguishable from found skin.

There is no defect more frequent than that of the hump, and it seldom happens that a woman who has a child with that deformity, does not endeavour to smooth it; either longed for a bare, or was frightened with a bare, or saw somebody with a bare hip; it is no matter what. A woman already prepossessed that there must have been some such cause, is not long at a loss for her memory, or her prejudice, soon furnishes her with a fact, and the instance of this child is added to the long catalogue of such.

It is not more than a century since some men of learning gave credit to the efficacy of sympathetic medicines, which, like other charms, were to communicate their virtues to patients at a distance. Learning and good sense have at length banished this visionary conceit; and in a century more, the notion of the *imagination* of the mother operating on the body of her unborn child, will meet with the same contempt. After all, the whole of this subject is not yet sufficiently explained. See FORTUNE, IMAGINIFER, among the Romans, an ensign-bearer, who carried the standard on which was represented the image of the reigning emperor. See SIGNS.

IMAGO, in Natural History, is a name given by Linnaeus to the third race of insects, when they appear in their proper shape and colours, and under no more transitory formation.

IMAM, or IMAN, a minister in the Mahometan church, answering to a parish priest among us.

The word properly signifies what we call a prelate; inferior, one who prelates over others; but the Mussulmen frequently apply it to a person who has the care and infallibility of a mosque, who is always there at first, and reads prayers to the people, which they repeat after him. IMAN is also applied, by way of excellence, to the four chiefs or founders of the four principal sects in the Mahometan religion.

Thus Ali is the imam of the Persian, or of the sect of the Schirites; Abu-bekker the imam of the Sunnites, which is the sect followed by the Turks; Saphi, or Saffi, the imam of another sect, &c.

The Mahometans do not agree among themselves about this *imamate* or dignity of the *imams*. Some think it of divine

divine right, and attached to a single family, as the pontificate of Aaron.—Others hold, that it is, indeed, of divine right, but deny A to be attached to any single family, as that it may not be transferred to another. They add, that the *imam* is to be clear of all gross sins; and that otherwise he may be deposed, and his dignity may be conferred on another. However this be, it is certain, that after an *imam* has once been owned as such, by the Mussulmans, he who denies that his authority comes immediately from God, is accounted impious; he who does not obey him, is a rebel; and he who pretends to contradict what he says, is esteemed a fool, among the orthodox of that religion. The *Imams* have no outward mark of distinction; their habit is the same with that of the Turks in common, except that the turban is a little larger, and folded somewhat differently.

IMAMIA, a name given to that sect of the Mahometans, to which the Persians adhere. See **ISLAM**.

IMBANKING, see **BANKING**.

IMBARGO, or **EMBARGO**, a stop or stay put upon ships, or merchandise, usually by public authority. See **EMBARGO**.

IMBATTLED, see **EMBATTLED**.

IMBECILITY, a state of languor or decay; wherein the body is not able to perform its usual exercises or functions.

IMBER, in *Orithology*, see **EMBER GUSE**, and **FLUDER**.

IMBEZLE, or **IMBEZZLE**, is probably from the old English word to waste, pilfer, or purloin.

As where a person intrusted with goods, wares, commodities, and diminishes them, he is said to *imbezle* them. Persons that *imbezle*, or illegally dispose of any woollen, linen, fustian, cotton, or iron materials; or gloves, leather, shoes, &c. with which they are intrusted for manufacture, shall forfeit double the value, or be sent to the house of correction, and there whipped, and kept for hard labour fourteen days; and for the second offence, forfeit four times the value, &c. Buyers and receivers are liable to the same penalties. 13 Geo. II. c. 8.

If any servant *imbezles*, purloins, or makes away his master's goods, to 40 shillings value, it is made felony without benefit of clergy, 12 Ann. c. 7. *Imbezling* the king's armour, or stores, is felony, by 31 Eliz. c. 4. other inferior imbezlements and misdemeanours of the same kind are punished with fine and imprisonment, by 1 Geo. I. c. 25. The usual method of proceeding against high officers who *imbezle* the public money is by impeachment in parliament. At common law the offender is subject to a discretionary fine and imprisonment. *Imbezling*, or vacating records, is a felonious offence against public justice, 8 Hen. VI. c. 12.

IMBIDE, is commonly used in the time sense as *absorb*, viz. where a dry porous body takes up another that is moist.

IMBLOCATION, in *Middle Age Writers*, a particular method of disposing of the dead bodies of excommunicated persons, by raising over them a heap of stones, or earth. This was done in the fields, or near high ways; it being unlawful to bury them in holy ground, or even to inter them at all. See **HOUZEL**.

The word is derived from *im*, tumultus.

IMERICATED, is used by some botanists, to express the figure of the leaves of some plants, which are hollowed like an *imbex*, or gutter-tile, or are laid in close series over one another like the tiles of a house.

IMBRICATED cup, *imbricatus calyx*, in *Botany*, a term used by authors to express the cups of some of the plants which have compound flowers; in which the common perianthium, surrounding the whole cluster of flowers, is composed of several series of squamæ, the exterior of which is short, and the interior longer, but in great part hid under these upper cups.

IMBRICATED shell, *imbricata concha*, in *Natural History*, a term used in general to express any species of shell-fish, whose shells are elevated into transverse ridges, lying over one another at the base, in the manner of the tiles on a house-top. It has also been used as the name of a peculiar species of shell: this is a *cardium* or heart-shell, whose sides are remarkably ridged in this transverse manner, and at the same time divided longitudinally by seven high ribs running from the apex to the edge, that the whole represents the roof of a house with the beams and rafters, before they are covered by the tiling. Hence the French call it *coquille*.

IMITATION, in *Musick*, a kind of composition wherein one part is made to imitate another, either throughout the whole piece, which is one of the kinds of canon, or only during some measures, which is a *single imitation*. Sometimes the movement, or the figure of the notes, alone, is imitated; and that, sometimes, even by a contrary motion, which makes what they call a *retrograde imitation*.

Imitation differs from *figure*, because in the former the repetition must be a second, a third, a fifth, seventh, or ninth, either above or below the first voice; whereas if the repetition were in unison, a fourth, fifth, or eighth, higher or lower, it would be a *figure*.

IMITATION, in *Oratory*, is an endeavour to resemble a speaker or writer in those qualities, with regard to which we propose them to ourselves as patterns. The first historians among the Romans, says Cicero, were very dry and jejune, till they began to imitate the Greeks, and then they became their rivals. It is well known how closely Virgil has imitated Homer in his *Æneid*, Hesiod in his *Georgics*, and Theocritus in his *Eclogues*. Terence copied after Menander; and Plautus after Epicurus, as we learn from Horace, lib. ii. ep. ad Augustum, who himself owes many of his beauties to the Greek lyric poets. Cicero appears, from many passages in his writings, to have imitated the Greek orators. Thus Quintilian says of him, that he has expressed the strength and sublimity of Demosthenes, the copiousness of Plato, and the delicacy of Isocrates. Inst. Or. lib. x. cap. 1. Writers on rhetoric have proposed three enquiries under the head of *imitatio*, viz. Who are to be imitated? What are to be imitated? and In what manner? With respect to the first we shall only observe, that in common cases it is not always what is absolutely best, but comparatively so in its own kind, and best suit their own taste, that should determine persons in the choice of their patterns for *imitation*: however, only the best writers, and those whom we may most safely trust, says Quintilian, are to be read long. With respect to the second enquiry, the things to be imitated are the perfections of the best masters in their several kinds; and these are different, according to the various subjects in which they excel. As to the manner of *imitatio*, it ought to be considered, that he who only copies or translates from another, and endeavours to pass it off for his own, is not an *imitator*, but a plagiarist. The true art of *imitatio* consists in so diversifying what we take from others, as if we can, to improve it, or at least not suffer it to receive any detriment by our alteration. And this may be done, by so enlarging a thought, or expression taken from another, as in a good measure to render it our own; by either abridging, or only taking a part of what another has said before us; by keeping the thought, and applying it to a different subject; and finally, by preserving the thoughts, and applying them to the same subject, but changing their order, and representing them in a different dress. See Ward's *Orat.* vol. ii. sect. 53 and 54.

IMMACULATE, *without stain*.—A term much used among the Romanists, when speaking of the conception of the blessed Virgin, they call it *immaculate*.

When the cap is given to a doctor of the Sorbonne, he is obliged to swear, that he will defend the *immaculate* conception. This was decreed by an act of the Sorbonne in the fourteenth century; in imitation of which, eighty other universities made the same order.

The military orders in Spain are all solemnly obliged to defend this prerogative of the Virgin. See **CONCEPTION**.

There is also a *Congregation of the Immaculate Conception*; in most nurseries whereof is a society of secular maids, whose end is to honour the *Immaculate conception*: of which they make a public procession every year, and a private one every day. See **TRINITATES**.

IMMANENT, in *Logic*.—The schoolmen distinguish two kinds of *actiones*; the one *transiens*, which pass from the agent to the patient; the other *immanens*, which continue in the agent.

IMMATERIALITY, abstraction from matter; or what we understand by pure spirit.

Plato proves the *immateriality* of the soul from these six topics. 1. Its simplicity. 2. Its independency on the body, which is twofold: in its *essence*, and in its *operation*, in existing, and in acting or operating separately. 3. Its rule and authority over the body. 4. Its likeness and similitude to God, which discovers itself in the pleasure it enjoys in spiritual things, in its aiming at spiritual objects, &c. 5. Its spiritual manner of perceiving material objects. And, lastly, its indivisibility, capacity, activity, and immortality. See **SOUL**.

IMMEDIATE, that which precedes or follows some other thing, without any interposition.

IMMEDIATE, also, signifies something that acts without means, or without medium. In which sense we say, *immediate grace*, and *immediate cause*, &c.

IMMEDIATE Mode. { **MODE**.
IMMEDIATE First. { **First**.

IMMEMORIAL, an epithet given to the time or duration of any thing whose beginning we know nothing of.

In a legal sense, a thing is said to be of time *immemorial*, or time out of mind, that was before the reign of our king Edward II.

IMMENSE, that whose amplitude, or extension, no finite mea-

measure whatsoever, or how oft soever repeated, can equal.

IMMERSION, an act by which any thing is plunged into water, or some other fluid.

In the first ages of Christianity, baptism was performed by immersion; by three immersions.—The custom of immersion is said to be still preserved in Portugal, and among the Anabaptists in other parts.

IMMERION, in Pharmacy, is the preparation of some medicine, by letting it steep for some time in water, in order to take from it quality or taste from it.

This is done in rhubarb, to moderate its force; in lime to take away its salt; and in olives, which are preserved in brine.

IMMERION, in Astronomy, is when a star or planet comes so near the sun, that we cannot discern it; being as it were enveloped, and hid in the rays of that luminary.

IMMERION also denotes the beginning of an eclipse of the moon; that is, the moment when the moon begins to be darkened, and to enter into the shadow of the earth.

The same term is also used with regard to an eclipse of the sun, when the disk of the moon begins to cover it.

In this sense, *immerion* stands opposed to *emersion*, which signifies the moment wherein the moon begins to come out of the shadow of the earth; or the sun begins to show the parts of his disk which were hid before.

IMMERION is frequently applied to the satellites of Jupiter, and especially to the first latitude; the observation whereof it is of much use for discovering the longitude.

The *immerion* of that satellite is the moment in which it appears to enter within the disk of Jupiter; and its *emersion* the moment wherein it appears to come out.

The *immerion* is observed from the time of the conjunction of Jupiter with the sun, to the time of his opposition; and the *emersion* from the time of his opposition to his conjunction.—The peculiar advantage of these observations is, that during eleven months of the year, they may be made, at least every other day.—The perfection of this theory, and the praxis thereon, we owe to M. Cassini.

Scraps of IMMERION, See *SCRUPLE*.

IMMERSUS *fugius*, in Anatomy, a name given by Richaud and some other authors, to a muscle since called the *INFRACAPSULARIS*.

IMMORTAL, that which will last to all eternity, as having in itself no principle of alteration, or corruption.

Plato defines immortality, *αὐτὸς ὡς καὶ αὐτὸς ποῦς, ἀμείωτος ὅπως καὶ ἀθάνατος*; and proves the immortality of the soul from two kinds of arguments; the one *artificial*, and the other *artificial*.

The *artificial* arguments for the soul's immortality are testimonies and authorities, whereof he cites several; and adds, in general, that all the great men and poets, who had any thing divine in them, have at all times asserted the immortality of the soul.

Artificial or proper arguments for the immortality are either *philosophical* or *practical*: of the first kind are those drawn from, 1. The simple, uniform, spiritual, and divine nature of the soul. 2. From its infinite capacity. 3. Its desiring and longing after immortality, and its inward horror of falling into nothing; proving it absurd that the soul should die, when life is its proper and adequate object. 4. Its rational activity; proving that whatever has in itself a principle of rational and spontaneous motion, by which it tends towards some supreme good, is immortal. 5. The various ideas which it has of spiritual things; particularly the idea it has of immortality; and, 6. Its immateriality.

His *practical* or moral arguments for the immortality of the soul, are drawn from, 1. The justice of God, which can never suffer the wicked to escape unpunished, nor the good unrewarded after death. 2. The dependence which religion has on this opinion, because, without this persuasion, there would be no religion in the world. 3. The crimes which men have, that justice and every kind of virtue are to be cultivated, that they may at last live with God. 4. The thirst of confidence, and anxious solicitude we are under about a future state.

IMMORTAL flower, in Botany. See *COMPRENSA*.

IMMUNITY, a privilege or exemption from some office, duty, or imposition.

Immunity is more particularly understood of the liberties granted to cities and communities.

The princes heretofore granted all kinds of *immunities* to ecclesiastics, exempting them from all impositions; but the ecclesiastics of those days were not so rich as those of ours: they gave all they had to the poor.

There is still a privilege of *immunity* in some places, and especially in Italy, belonging to ecclesiastical things, and persons; who are exempted from certain taxes, and are sheltered from the pursuits of justice. Though there are

some crimes for which they cannot plead the privilege of their *immunity*, as premeditated murder, &c.

IMMUTABILITY, the condition of a thing that cannot change.

Immutability is one of the divine attributes. See *God*.

IMPALED, in Heraldry, is understood of a shield partly per pale, or divided into two halves by a line drawn palewise through the middle, from the top to the bottom.

When the coats of arms of a man and his wife, who is not an heiress, are borne in the same escutcheon, they must be *impaled*, or marshalled in pale, i. e. the husband's on the right side, and the wife's on the left; and this the heralds call *baron and fesse*, two coats *impaled*.

If a man have had two wives, he may *impale* his coat in the middle between theirs; and if he have had more than two, they are to be marshalled on each side of his in their proper order.

IMPALEMENT, in a final fence. } See *EMPALEMENT*.

IMPALEMENT, in Physiology, } See *EMPALEMENT*.

IMPALEABLE, that whole parts are so extremely minute, that they cannot be distinguished by the senses, particularly by that of feeling.

IMPANATION, formed of *in* and *panis*, bread, a term used among divines to signify the opinion of the Lutherans with regard to the eucharist; who believe that the species of bread and wine remain, together with the body of our Saviour, after consecration. See *CONSUBSTANTIATION*.

IMPANATOIRES. See *ADESSENAIR*.

IMPANNELING, in Law. See *EMPAANNELING*.

IMPARES *Scamilli*. See *SCAMILLI*.

IMPARLANCE. See *EMPARLANCE*.

IMPARSONEE, in Law, is applied to a person that is induced, and in possession of a benefice.

IMPASSIBLE, that which is exempt from sufferings; or which cannot undergo pain, or alteration.

The Stoics place the soul of their wise man in an *impassible*, imperturbable state. See *APATHY*.

IMPASTATION, the mixture of divers materials of different colours, and consistencies, baked or bound together with some cement, and hardened either by the air, or fire.

IMPASTATION is sometimes used for a sort of mason's work, made of stucco, or stone ground small, and wrought up again in manner of a pale.

Authors are of opinion that the obelisks, and the huge antique columns still remaining, were made, some by *impastation*, and others by fusion; but this is wholly erroneous: they are all cut out of quarries, yet open in Egypt, Arabia, &c.

IMPASTING, in Painting. See *EMPASTING*.

IMPATIENS, in Botany. See *BALSAMINA*.

IMPEACHMENT, from the Latin, *impetere*, to set on, or attack; or rather from the French, *impecher*, to hinder, in Law, is the accusation and prosecution of a person for treason, or other crimes and misdemeanors.

Any member of the lower house of parliament may impeach any one belonging either to that body, or the house of lords. The method of proceeding is to exhibit articles on the behalf of the commons, by whom managers are appointed to make good their charge. These articles are carried to the lords, by whom every person impeached by the commons is tried; and if they find him guilty, no pardon under the great seal can be pleaded to such an impeachment. 12 and 13 Will. III. c. 2. A commoner cannot, however, be impeached before the lords for any capital offence, but only for high misdemeanors.

A peer may be impeached for any crime; the crimes of impeachment are a kind of bills of indictment, passed by the house of commons, and afterwards tried by the lords, who, in cases of misdemeanors, are considered not only as their own peers, but as the peers of the whole nation.

This custom is derived from the constitution of the ancient Germans, who, in their great councils, sometimes tried capital accusations relating to the public.

Acta et consilia necesse fore, et de iurisdictione imperatoris. Tacit. de Mor. Germ. 12. Black. Com. vol. iv. p. 259, &c.

IMPEACHMENT of Waste, a restraint from committing of waste upon lands and tenements; or a demand of recompense for waste made by a tenant who has but a limited estate in the land granted.

He that hath a lease without *impachment of waste*, hath by that a property or interest given him in the houses and trees, and may make waste in them without being called to an account for it.

IMPECCABLES, in Church History, a name given to those heretics, who boasted that they were *impeccable*, and that there was no need of repentance: such were the Gnostics, Priscillianists, &c.

IMPECCABILITY, the state of a person who cannot sin; or a grace, privilege, or principle which put him out of a possibility of sinning.

The schoolmen distinguished several kinds and degrees of *improbability*: that of God, belongs to him by nature: that of Jesus Christ, considered as man, belongs to him by the hypochondriacal union: that of the blessed, is a consequence of their condition: that of men, is the effect of a confirmation in grace, and is rather called *impossibility* than *improbability*; accordingly divines distinguish between these two: this distinction is found necessary in the disputes against the Pelagians, in order to explain certain terms in the Greek and Latin fathers, which without this distinction are easily confounded.

IMPEDIMENTS, in *Law*, are such hindrances as put a stop or stay to a person's seeking for his right by a due course of law. Persons under *impediments* are those under age, or coverture, *non compos mentis*, in prison, beyond sea, &c. who, by a living in our laws, have time to claim, and protect their rights, after the impediments are removed, in case of fines levied, &c.

IMPEDIMENTS of marriage, see **MARRIAGE**.

IMPEDIT, in *Law*. See **QUARE IMPEDIT**.

IMPERMEABILITY, a quality whereby a thing becomes unable to be pierced or penetrated; or a property of body whereby it fills up certain spaces, so that there is no room in them for any other body.

Dr. Harris defines *impermeability*, the distinction of one extended substance from another, by means whereof the extension of one thing is different from that of another: so that two extended things cannot be in the same place, but must necessarily exclude each other. See **SOLIDITY**.

IMPERVIOUS, or **IMPERVIABLE**, a hardness of heart, which makes a person persevere in vice, and prevents his repentance.

IMPERVATIVE, in *Grammar*, is one of the moods or manners of conjugating a verb, serving to express a commandment as, *veni, curre, &c.* The *imperative*, according to bishop Wilkins, is one of the primary moods, or moods, the indicative being the other: by this the speaker expresses his will to him that has the thing in his power; namely, to his superior by petition, to his equal by persuasion, and to his inferior by command; and the manner in which these affect the copula (be it so, or let it be so) is called the *imperative mood*, of which there are three varieties. Wilkins's Real Character, part iii. c. 7. The same distinction is observed by Mr. Harris, who makes the *imperative mood* a species of the *requisite* when applied to inferiors; but when pertaining to equals, or superiors, it is a precatory or optative. Hermes, p. 124, ed. 2d. See **MOOD**.

In Hebrew, and other oriental languages, the future tense has frequently an *imperative* signification.

IMPERATOR, among the *Romans*, a title of honour given to generals after a victory; first by the acclamations of the soldiers, and afterwards confirmed by the senate. See **EMPEROR**.

IMPERATORIA, in *Italy*, see **MASTERWORD**.

IMPERATRIN, in *Italy*, a name given by some authors to the queen, or **QUEEN**.

IMPERVECT Plants, among *Botanists*, are such as either really want flower and seed, or are supposed to want them: no flower or seed having been discovered in the greater part of those plants included in this class by the botanical writers, at the time when they were thus designated. See **IMPERFECT PLANTS**.

IMPERFECT chord, in *Music*, see **CONCORD**.

IMPERFECT flower. See **FLOWERS** and **STAMINEOUS**.

IMPERFECT mints. See **MINT**.

IMPERFECT numbers, in *Arithmetic*, see **NUMBERS**.

IMPERFECT tense, in *Grammar*, signifies an indefinite time between the present and the past; as, *I taught, I heard*. The *imperfect* was sometimes employed by the ancients to denote what is usual and customary: thus *scilicet* and *scilicet* signify not only *he was rising, he was writing*, but upon occasion they signify, *he used to rise, he used to write*. The reason of this is, that whatever is customary, must be something which has been frequently repeated; but what has been frequently repeated must require an extension of time past. It was also used by the ancients, in which they have been followed by the moderns, in a suspensive kind of inscription; as *scilicet*, *scilicet*, *scilicet*, but not *scilicet* or *scilicet*; by which use of the *imperfect* they avoid the show of ignorance, and had prepared an apology in case of censure, by saying that the work was *scilicet* *scilicet* in hand, without pretending that it was *scilicet* *scilicet*. Harris's Hermes, p. 126, &c. See **TERM**.

IMPERFORATE anus. See **ANUS** and **INFANT**.

IMPERIAL, something belonging to an emperor, or empire.

Thus we say, his *imperial majesty*, the *imperial crown*, *imperial medals*, the *imperial chamber*.

IMPERIAL cities, in Germany, are those which own no other head but the emperor.

These are a kind of little commonwealths; the chief magistrates whereof does homage to the emperor, and pays him the Roman money; but in other respects, and in the administration of justice, the magistrate is sovereign.

The *imperial cities* have a right of coining money, and of keeping forces, and fortified places: their deputies sit at the *imperial diets*, where they are divided into two branches; that of the Rhine, and that of Swabia. There were formerly twenty-two in the former, and thirty-seven in the latter; but there are now only forty-nine in all; thirteen belonging to the former, and thirty-six to the latter.

IMPERIAL diet, is an assembly or convention of all the states of the empire. See **DIET**.

The diet is divided into three colleges, and each college has its *elector*, who presides in the consultations: the elector of Mentz, in the college of electors; the archbishop of Salzburg, and archbishop of Austria, in that of the princes, and the deputy of the city of Cologne, or of any other, in that of the cities.

In the diet, each principality has a voice; but all the prelates (so they call the abbots and provosts of the empire) have but two voices, and all the counts but four.

Though the three colleges agree, yet the emperor has a negative voice: when he also consents, the resolutions pass into a law, which obliges all the states of the empire, both mediate and immediate.

IMPERIAL salt, *imperiale sal*, a term used by some of the old writers to express the common salt gemme; and used, by others, for the *sal ammoniacum*.

IMPERIAL salt, in *Surgery*, an instrument made of brass, with a box and needle, &c. used in measuring land.

IMPERII census. See **RECEIPIUS IMPERII**.

IMPERSONAL verb, in *Grammar*, is such an one, as is only used in the third person singular; as *aperit, licet, &c.* Every verb, says the ingenious Mr. Harris, whether active or passive, has in language a necessary reference to some noun for its nominative case; and the doctrine of *impersonal verbs* has been fully rejected by the best grammarians, both ancient and modern. Hermes, p. 175.

IMPERVIOUS, a thing not to be perceived, or passed through; either by reason of the closeness of its pores, or the particular configuration of its parts.

IMPETIGO, in *Medicine*, an extreme roughness, and foulness of the skin, attended with an itching, and plentiful scurf.

In which sense it amounts to the same with *lichen, scabiosa, and montana*.

The *impetigo* is a species of dry, pruriginous itch, wherein scales or scurf succeed apace, arising from saline corrosive humours thrown out upon the exterior habit of the body, by which means the internal parts are usually relieved.

It is divided into *milis*, mild, not accompanied with any malignity; and *sera*, severe, which comes near to a leprosy. See **FRECK** and **LEPROSY**.

IMPERATION, the act of obtaining any thing by request or prayer.

IMPERATRICE was more particularly used in our statutes for the pre-obtaining of benefices and church-offices in England from the court of Rome, which did belong to the disposal of the king, and other lay patrons of the realm; the penalty whereof is the same with that of provisors, 25 E. III. See **PROVISOR**.

IMPETUS, in *Mechanics*. See **FORCE**, **MOMENTUM**, and **MOTION**.

Paracentric IMPETUS. See **PARACENTRIC**.

IMPING, in *Falconry*, the inserting a feather in the wing of a hawk, in the place of one that is broken.

IMPLANTATION. See **TRANSPANTATION**.

IMPLEAD, to sue, or prosecute by course of law. See **PLEADING**.

IMPLEMENTS, formed either from the Latin *impleto*, to fill up; or from the French *impler*, to employ; is used for all things necessary for a trade, or the furniture of an household.

In this sense we frequently find it used in wills, and conveyances of moveables.

IMPLEX action. See **ACTION**.

IMPLICATION, in *Law*, is where the law doth imply something, that is not declared between parties, in their deeds and agreement; and when our law giveth any thing to a man, it giveth *implicitly* whatever is necessary for the enjoying the same. The want of words may be helped in some cases by *implication*; and to one word or thing, or one estate given, shall be implied by another; and there is an *implication* in wills and devises of lands, whereby estates are gained.

IMPLICIT, derived from *in*, and *plere*, I fill; something tacitly comprised, or understood: that is, contained in a discourse, clause, or proposition, not in express terms, but only by induction and consequence.

Implicit faith. See **FAITH**.

IMPLICIT resolution. See **CONDITION.**

IMPLY a contradiction, a phrase used among philo'sophers, in speaking of the object of divine omnipotence.

God can do every thing that does not imply a contradiction proceeding from God: by which it is not meant a restriction of the action to the executive power of God, but a relation to the other attributes and simple perfections of God.

IMPORTANCE of action. See **ACTION.**

IMPORTATION, the act of importing or bringing merchandise from foreign countries, in contradistinction to **EXPORTATION.**

Some of the principal statutes relating to the *importation* of merchandise, are 12 Car. II. c. 4.—12 Car. II. c. 19. 14 Car. II. c. 11.—4 and 5 W. and M. c. 5.—6 W. and M. c. 1.—7 and 8 W. and M. c. 28.

Concerning goods prohibited from being *imported*, see Stat. 2 Edw. IV. c. 4.—1 Rich. III. c. 12.—13 and 14 Car. II. c. 17.—18 Car. II. c. 37.—9, and 10 W. III. —21 Geo. II.—Ann. c. 27.

IMPOSITION of hands, an ecclesiastical action by which a bishop lays his hand on the head of a person, in ordination, confirmation, or in uttering a blessing. This practice is also frequently observed by the Dissenters at the ordination of their ministers, when all the ministers present place their hands on the head of him whom they are ordaining, while one of them prays for a blessing on him and his future labours. This form of them retain as an ancient practice, justified by the example of the apostles, when no extraordinary gifts are conveyed. However, they are not agreed as to the propriety of this ceremony; nor do they consider it as an essential part of ordination.

Imposition of hands was a Jewish ceremony, introduced, not by any divine authority, but by custom: it being the practice among those people, whenever they prayed to God for any person, to lay their hands on his head.

Our Saviour observed the same custom, both when he conferred blessing on children, and when he cured the sick by adding prayer to the ceremony. The apostles likewise laid hands on those upon whom they bestowed the Holy Ghost.

The priests observed the same custom when any one was received into their body.—And the apostles themselves underwent the *imposition of hands* abroad, every time they entered upon any new design. In the ancient church, *imposition of hands* was even practised on persons when they married; which custom the Abyssinians still observe.

But this term, which, in its original signification, is general, is now restrained, by custom, to that *imposition* which is practised at ordination. Spahnheim has written a treatise *De impositione manus*; and Tribenhorius and Brunius have wrote the same. See *Imposition of HANDS*, and **ORDINATION.**

IMPOSITION of tongue, &c. See **DUTY, &c.**

IMPOSSIBLE, that which is not possible, or which cannot be done or effected. A proposition is said to be *impossible*, when it contains two ideas which mutually destroy each other, and which can neither be conceived, nor united together in the mind.

Thus it is *impossible*, that a circle should be a square; because we conceive clearly, that squareness and roundness destroy each other by the contrariety of their figure.

There are two kinds of *impossibilities*, *physical* and *moral*.

Physical impossibility, is that which is contrary to the laws of nature.

A thing is *morally impossible*, when of its own nature it is possible, but yet is attended with such difficulties, as that, although considered, it appears *impossible*.

Thus it is *morally impossible*, that all men should be virtuous; or that a man should throw the same number with three dice a hundred times successively.

A thing which is *impossible* in law, is the same with a thing *impossible* in nature; and if any thing in a bond or deed be *impossible* to be done, such deed, &c. is void. 21 Car. I. II. B.

IMPOSSIBLE quantity, in *Algebra*. See **ROOT.**

IMPOST, from *imponere*, *I impose*, in *Law*, properly denotes the tribute or tax appointed by a sovereign to be paid for such merchandise as is brought into any haven in his dominions from foreign nations. See **DUTY.**

Impost is distinguished from *custom*, in that custom more properly signifies the duties paid to the king for goods shipped off or exported. But the two are frequently confounded together.

IMPOSTHUME, by corruption from *impossem* and *ossem*, *assess*, a collection of matter, or pus, in any part of the body, either owing to an obstruction of the fluids in that part, which makes them change into such matter; or to a translocation of it from some other part where it was generated. See **ABSCESS.**

IMPOSTORS, *religiosi*, are such as falsely pretend to an extraordinary commission from Heaven; and who terrify and abuse the people with false denunciations of judg-

ments. These are punishable in the temporal courts with fine, imprisonment, and infamous corporal punishment.

IMPOSTS, in *Architecture*, the capitals of pillars, or pilasters, which support arches. See *Tab. Arch. fig. 40, B.* An *impost*, sometimes also called *chapital*, is a sort of little corner, which crowns a pier, and supports the first floor whence the arch or vault commences.

Imposts conform to their proper orders.—The Tuscan is a plain only; the Doric has two faces crowned; the Ionic has a banner, over the two faces, and its mouldings may be varied; the Corinthian and Composite have a banner, foliage, and other moulding.

The profile of the *impost* must not exceed the width of the pillar. Sometimes the entablature of the *impost* serves for the *impost* of the arch; and this looks very grand and stately.

The *impost* is a thing essential to an ordonnance; much so without it, in the place where the curve of the arch meets with the perpendicular line of the pier, there always seems a kind of elbow.

P in fig. 20, represents an *impost* made open or flat in the middle, and bounded by fillets or ogee. This kind of *impost* is said to be the invention of lord Burlington, and is by many called a *Burlington impost*. It is enriched with a *quatrefoil*, or bands forming circles and intersecting each other: when there are two rows, it is called a double *quatrefoil*.

The following rules are given by some modern authors for dividing the *imposts* of arches: in the *Tuscan impost*, the face hath 3 parts, the ogee 1, the fillet 1, the corona 3, and the band 12. For the projections, the fascia 1, the ogee 2 parts, corona 3, and the whole 31.

In the *Doric*, the frieze 2, fillet 1, astragal 2, cyma recta 2, fillet 1, corona 2, ogee 1. For the projections, fillet 1, astragal 1, corona 2, and the whole 32.

In the *ionic*, fillet 1, cyma 4, ovolo 1, corona 1, ogee 1. For the projections, cyma 12, corona 2, the whole 35.

In the *Corinthian*, the frieze 1, fillet 1, astragal 1, cyma 1, ovolo 1, corona 1, ogee 1. For the projections, fillet 1, astragal 1, cyma 1, corona 2, the whole 34.

In the *Composite*, frieze 2, fillet 1, astragal 1, ovolo 1, cyma 1, corona 1, ogee 1. For the projections, fillet 1, astragal 1, ovolo 1, cyma 2, corona 2, the whole 36.

IMPOWERENCE, or **IMPOWERY**, derived from the proposition *ire*, taken privatively, and *potens*, *potens*, a want of strength, power, or means, to perform any thing. Divines and philosophers distinguish two kinds of *impotency*, *natural* and *moral*.—The first is want of some physical principle necessary to an action; or it is where a being is absolutely defective, or not free, and at liberty to act: the second only imports a great difficulty, or strong habit to the contrary; a violent passion, inclination, or the like.—*Impotency* is more particularly a natural inability to coition.

In this sense, *impotency* is defined an inability to coition in the male to impregnate the female.

We have instances of *impotency* for general causes, as from an impediment to the ejection of the semen, or from a wrong direction, which the orifices of the vas deferens get, whereby the seed was thrown into the bladder. Mr. Petit cured one patient under such a difficulty of emission, by making an incision like to that commonly made in the great operation for the stone. See *Nouv. de l'Acad. de Chirurg. tom. I.*

Impotency may be caused by various accidents, but most frequently takes its rise from early and immoderate venery; and often from the venereal disease.

Impotency is a canonical disability, to avoid marriage in the spiritual court. The marriage is not void of itself, but voidable only by sentence of legislation, during the life of the parties.

IMPRACICABLE *case*, in *Algebra*. See **IMPRACICABLE**.

IMPRECATION, derive from *in*, and *precare*, *I pray*, a curse, or wish that some evil may befall any one.

The ancients had their goddesses called *Imprecatrices*, in Latin *Dire*, i. e. *Direrum*, who were supposed to be the executors of evil consciences. They were called *Dire* in heaven, *Furies* on earth, and *Erinnyes* in hell. The Romans owned but three of these *Imprecatrices*, and the Greeks only two. They invoked them with prayers, and pieces of verses, to destroy their enemies.

IMPREGNATION, derived from *impregnare*, of *pregnans*, a woman with child; the emission of the seed of the male in coition, by which the female conceives, or becomes with young. See **GENERATION.**

IMPREGNATION is also figuratively used in pharmacy, when a liquor imbues the particles of some other body.

Thus a menstruum is said to be *impregnated* with a body dissolved in it, as much as its pores are able to receive.

IMPRESSED species. See **SPECIES.**

IMPRESSING, in the *Sea Language*. See **MANNING** the *Ship*.

IMPRESSION, in *Philosophy*, is applied to the species of objects which are supposed to make some mark or impression on the senses, the mind, and the memory.

The Peripatetics tell us, that bodies emit species resembling them, which species are conveyed by the exterior senses to the common sensorium; these *impressed* species, being material and sensible, they say, are rendered intelligible by the active intellect; and, when thus spiritualized, are called *essences*, or *species speciei*, as being extracted from the others.

IMPRESSION is also frequently used in speaking of the editions of a book, or of the number of times it has been printed.

Impressus, however, differs from *editus*: the former, properly speaking, takes in no more than what belongs to the printing, the letter, paper, margin, page, distance of words and lines, and the disposition of every thing that may have a good or bad effect upon the eye: the latter, besides all this, takes in the care of the editor, who has revised the copy, corrected or augmented it, adding notes, tables, and other like things, which he judged might contribute towards making the book more useful and correct.

Indeed very frequently the word *editio* only refers to this latter part, as when, in speaking of the works of St. Augustine, we quote the edition of Erasmus, the Lovanium, Benedictine, &c. where we have no regard to the printing part, but only to the care and pains of the editors.

Privilege for IMPRESSION. See **PRIVILEGE**.

IMPRESSIONS on *gens* and *midals*. See **GEMS** and **MIDALS**.

IMPRESS, *Auditors of.* See **AUDITORS**.

IMPRISONMENT, the state of a person restrained of his liberty, and detained under the custody of another, and extends not only to a GAOL, but to a house, stocks, or a man's being held in the street, &c. None shall be imprisoned but by the lawful judgment of his peers, or by the law of the land. Mag. Ch. 9 Hen. III. c. 2. 25 Edw. III. ff. 5. c. 4.

No person is to be imprisoned but as the law directs, either by the command or order of a court of record, or by lawful warrant; or the king's process, on which one may be lawfully detained. And at common law, a person could not be imprisoned unless he were guilty of some force and violence, for which his body was subject to imprisonment, as one of the highest executions. Where the law gives power to imprison, in such case it is justifiable, provided he that does it in pursuance of a statute, exactly pursues the statute in the manner of doing it, for otherwise it will be deemed false imprisonment, and in consequence it is unjustifiable. Every warrant of commitment for imprisoning a person, ought to run, "I do deliver by due course of law," and not "Under further order," which has been held ill, and thus it also is, where one is imprisoned on a warrant not mentioning any cause for which he is committed.

A person being sent to prison by a warrant from a feynor of state, without alleging any cause, &c. it was adjudged, that he ought to be discharged for that reason. Persons may also, by bail or habeas corpus, be discharged from their imprisonment in any case bailable. See the articles **HABEAS CORPUS**, **BAIL**, **PRISON**, **PRISONER**, and **GAOL**.

False IMPRISONMENT. See **FALSH**, and **APPEAL**.
IMPRISONPTU. See **IMPRISONPTU**.
IMPROPER *rationis.* See **FRACTIONS**.
IMPROPRIATION, is a term used where the profits of an ecclesiastical benefice are in the hands of a layman. In which sense it stands distinguished from **APPROPRIATION**, which is where the profits of a benefice are in the hands of a bishop, college, &c. though the two are now often used promiscuously.—There are said to be 3845 appropriations in England.

IMPROPRIETY, the quality of something that is not fit, or proper. See **PROPER**, and **PROPRIETY**.

Grammars observe three kinds of faults in language; a **SOLICISM**, **BARBARISM**, and **IMPROPRIETY**: an *impropriety* is committed when a word is used that has not a proper signification.

IMPROVIDE, in *Law*. See **QUA IMPROVIDE**.

IMPULSIVE, a term in philosophy, applied to the action of the body which impels or pushes another.

Thus the arm is said to give an *impulsive* motion to the stone that it throws. See **PROJECTILE**.

In this sense, *impulsive* hands, contradistinguished from *attractive* and *repulsive*.

Sir Isaac Newton suggests, that attraction itself may possibly be effected by an *impulsive* power.

IMPURITY, in the *Mosaic law*. There were several sorts of *impurity* contracted under the law of *Moses*. Some were voluntary, as the touching of a dead body, or of

any animal that died of itself or of any creeping thing; or unclean creature; or the touching things holy by one who was not clean, or was not a priest; or touching persons under *impure* circumstances. Other kinds of *impurity* there were, of an involuntary nature; for which we must refer the reader to Calmet, who shows what kind of purification was prescribed for each species of pollution. See **NUMB. xix. 11, 14.** **LEVIT. xi. 24, 43.** **LEVIT. xii. 23, 45.** **1st. xv. 25.** **CALM. DICTION. BIBL. in voc.**

IMPUTATION, a term much used among divines, sometimes in a good, and sometimes in an ill sense: in the latter it is used to signify the charging the sin to the account of one, which was committed by another. The word, however, is generally used in an ill sense; for when we place any good to the account of another, we use the word *attribute*.

Thus Adam's sin is said by some divines to be *imputed* to all his posterity; all his descendants, by his fall, becoming as criminal in the sight of God, as if they had fallen themselves; and bearing the just punishment of his first crime. See **ORIGINAL SIN**.

Imputation, used in a good sense, signifies the charging of another's justice, or merit.

Thus the justice of Jesus Christ is said to be *imputed* to us, his merits, and the price of his suffering, being applied to us.

IN, in the *Managers*,—*To put a horse in*, is an expression that signifies to breed and dress him; by putting him right upon the band and the heels.

IN, in the *Sea Language*, denotes the state of any of a ship's sails, when they are furled or blown; it is used in opposition to *out*, which implies that they are set, or extended to assist the ship's course.

In-penny and out-penny, in *Our Old Priests*, money paid by the custom of some manors on the alteration of tenants. See—*In-penny and out-penny consuetudo talis est in villa de East Radham, de omnibus terris qua infra Berghemium tenentur, viz. quod ipse, qui vendidit vel dedit dictam tenentiam alieri, dabit pro exitu suo de eadem tenura annum denarium, et simili de ingressu aliorum; et si prolati denarii a retro fuerint, hollivus domini deditur pro eisdem denariis in eadem tenura.* Regillit. Prior. de Cokesford, p. 25.

INACCESSIBLE *depth, or distance.* See **ALTITUDE**, **DISTANCE**, &c.

INACHIA, *Inopia*, in *Antiquity*, a festival in Crete, celebrated in honour of Leucothea, or Ino.

The word is compounded of *Ino*, and *gria*, i. e. grief; being perhaps a commemoration of Ino's misfortune.

INACTION, *cessatio* of *action*, a term much used in the mystical divinity; by which is understood a privation, or annihilation, of all the faculties whereby the soul is, as it were, shut to all external objects, and a kind of castly is procured, during which God speaks immediately to the heart. It is the state of *inaction* that is held the most proper for receiving the Holy Spirit; and in this fit of dozing, they say, it is that God communicates sublime and ineffable sentiments and graces to the soul.

Some do not make it consist in this stupid kind of indolence, or general suspension of all sensation: but by *inaction* only mean a cessation of desires, in which, as the soul does not determine itself to any positive acts, neither does it abandon itself to useless meditations, or the vain speculations of reason; but demands in general every thing that may be agreeable to God, without prescribing any thing to him.

This latter is the doctrine of the ancient mystics, and the former that of the modern ones, or the quiescents.

In general, however, it may be said, that *inaction* is not the most likely way of pleasing God; by our actions chiefly we are to gain his favour; he will have us to act; so that *inaction* cannot be agreeable to him.

INACTIVITY of matter. See **VIS INERTIA**.

INADEQUATE *idea, or notion*, is a partial or incomplete representation of any thing to the mind. See **IDEA**.

INAJA guacota, in *Ritay*, a name by which some authors have called the cocoa-nut tree, or *palma indica nuxifera* of other writers.

INALIENABLE, that which cannot be validly alienated, or made over to another. See **ALIENATION**.

Thus the dominions of the king, the church, minors, &c. are *inalienable*, otherwise than with a reserve of the right of redemption for ever.

INAMBUCLIA, in *Natural History*, the name of a genus of fish, of the class of the *scorpeni*; but of the number of the columnar, not the rhomboidal kinds, and composed merely of parallel fibres. See **SALICUTER**.

INAMILLING, or **EWAMELLING**. See **EWAMELLING**.

INANIMATE, derived from *in*, taken privately, and *anima*, *fiat*, denotes a body that has either lost its soul or that is not of a nature capable of having any. Thus, a dead man is an *inanimate* lump; and metals are *inanimate* bodies.

INANITION, a term in *Physic*, signifying emptiness, or the state of the stomach, when it is empty, and needs food.

There are flatulencies which proceed from repletion, and others from *inanities*, which last are the more dangerous.

INANITY, the school term for emptiness or absolute vacuity, and implies the absence of all body and matter whatsoever, so that nothing remains but mere space.

INARCHING, in *Gardening*, a particular sort of grafting, called also by some grafting by approach. It is used when the stock intended to be grafted on, and the tree from which the graft is to be taken, stand by near one another, that they may be brought to touch. The branch to be inserted is to be fixed to that part of the stock where it is to be joined, the root and wood are to be pared away on one side for the length of three inches, and the stock or branch where the graft is to be united is to be fayed in the same manner, so that the two may join equally together, and the sap meet; a little taupec is then to be cut upwards in the graft, and a notch made in the stock to admit it, so that when they are joined, the tongue will prevent their slipping, and the graft will more closely unite to the stock. Having thus brought them exactly together, they must be tied with some ball or work, or, on both sides, and then the place must be covered with some grafting clay, to prevent the air from drying the wound, and the wet from rotting the stock; a stake must be fixed in the ground, to which both the stock and the graft must be tied, to prevent the winds displacing them. When they have remained in this state four months, they will be sufficiently united, and the graft may then be cut off from the mother-tree, observing to slope it close to the stock, and at this time there should be fresh clay laid all round the part. This operation should be performed in April or May, that the graft may be perfectly united to the stock, before the ensuing winter. It is principally practised upon oranges, myrtles, lemon-trees, walnuts, and firs, and some other trees, which do not succeed well in the common way of grafting. But it is a wrong practice when orange-trees are designed to grow large, for these are seldom long-lived after the operation. See **ARCTATOP** and **ENGRAFTING**.

INARTICULATE, an epithet applied to such sounds, syllables, or words, as are not pronounced distinctly. See **ARTICULATE**.

INAUGURATION, the consecration of an emperor or king; or the consecration of a prelate, so called in imitation of the ceremonies used by the Romans, when they were received into the college of augurs. See **CROWN**, **KING**, and **BISHOP**.

The word comes from the Latin *inaugurare*, which signifies to dedicate a temple, or to raise any one to the priesthood, having, in order to that, first taken auguries. See **AUGUR**, and **AUGURY**.

INCA, or **YACA**, an appellation which the natives of Peru give to their kings, and princes of the blood.

The chronicle of Peru relates the origin of the *incas*: this country had been a long time the theatre of all sorts of wars, horrible crimes, and dissensions, till at length there appeared two brothers, the one of whom was called *Manco Capac*: of this person the Indians use to tell wonders; they say he built the city of Cuzco, settled laws and policy, and taught them to adore the sun: and he and his descendants took the name of *inca*, which, in the language of Peru, signifies *king*, or *great lord*. These *incas* grew so powerful, that they made themselves masters of the whole country, from Chili to Quito, establishing in every province their peculiar policy and religious institutions, and held it till the divisions between the brothers Huascar and Atahualpa; which the Spaniards under Pizarro having held off, made themselves masters of Peru, and put an end to the empire of the *inca*, in 1533. They number only twelve of these *incas*. It is said, the most considerable among the nobles of the country still bear the name of *inca*.

INCALESCENCE, compounded of *in*, and *caleo*, or *calere*, *Igeris* warm, the growing hot of any thing, either by motion and friction, or as quick-lime does by putting water on it.

INCALESCENT *mercury*, a name given by Mr. Boyle to some mercuries of an uncommon preparation, which, by being mingled with a due proportion of gold-leaves, or small filings, would amalgamate and grow hot with the gold.

INCAMERATION, derived from *in*, and *camera*, *chamber*, in the *apophyseal* church, the union of some land, right, or revenue, to the domain of the pope. See **CHAMBER**.

INCANTATION, derived from the Latin *in*, and *canto*, *I say*, (see **CHARM**, and **CARMEN**), *enchantment*; words and ceremonies used by magicians to raise devils; or rather to impose on the credulity of the people. See **CON-**

JURATION, **FACINATION**, **MAGIC**, **WITCHCRAFT**, &c.

INCAPACITY, in matters of benefices among the canonists, is of two kinds: the one renders the provision of a benefice null in its original; the other is *accidens*, and annuls the provisions which at first were valid.

Incapacity of the first kind, are the want of a dispensation for age in a minor, for legitimation in a bastard, for naturalization in a foreigner, &c.

Of the latter kind, are various offences and crimes as being concerned in feigning a sentence of death executed. See which they decree, vacate the benefice to all intents, or render the holding it irregular.

INCARNATION, in *Theology*, signifies the act whereby the Son of God assumed the human nature, or the flesh, by which Jesus Christ, the eternal word, became man, in order to accomplish the work of our redemption. The era used among Christians, whence they number their years, is the time of the *incarnation*, that is, of Christ's conception in the virgin's womb.

This era was first established by Dionysius Exiguus, about the beginning of the sixth century, till which time the era of Diocletian had been in use.

Some time after this, it was considered, that the years of a man's life were not numbered from the time of his conception, but from that of his birth: which occasioned them to postpone the beginning of this era, for the space of one year, retaining the cycle of Dionysius entire, in every thing else.

At Rome they reckon their years from the *incarnation*, or birth of Christ; that is, from the 25th of December, which custom has obtained from year 1531. In France, and several other countries, they also reckon from the *incarnation*; but then they differ from each other in the day of the *incarnation*, fixing it, after the pominive manner, not to the day of the birth, but conception of our Saviour. Though the Foretellers retain the day of the birth, and begin their year from Christmas. See **PETAV. DE DOCT. TEMP.** **GRANDIENUS DE DEI NAT.** See **ERA** and **EROGIA**.

INCARNATION, formed from *in*, and *caro*, *flesh*, in *Surgery*, signifies the healing and filling up ulcers and wounds with new flesh.

INCARNATIVE, in *Medicine* and *Surgery*, is applied to medicines, bandages, &c. which dispose a wound or ulcer to fill up with flesh. Whence they are also called *anagregativa*, from *anag*, again, and *agregare*, to fill.

INCARNATIVE medicine, is such an one as makes the flesh heal and unite.

INCARNATIVE bandage. See **BANDAGE**.

INCARNATIVE spirit. See **SUTURE**.

INCARTATION, in *Chimistry*, the refining of gold, by means of filver, and aqua fortis.

This is the same with what is otherwise called *assay*. See **DEPART**.

INCENDIARY, *incendiariorum*, in *Law*, is applied to a person who is guilty of maliciously setting fire to another's house, and all out-houses that are parcelled out, though not contiguous to it nor under the same roof, barns and stables. A bare intent, or attempt to do so, by actually setting fire to a house, unless it absolutely burns, does not fall within the description of *incendiariorum*. But the burning and consuming of any part is sufficient; though the fire be afterwards extinguished. It must also be a malicious burning; otherwise it is only trespass. This offence is called *arson* in our law.

Among the ancients, criminals of this kind were to be burnt. *Qui autem, accensusque framenti jussu domus populum sceleris, gradensque dale male combustoris, vinctus igni necatur.*

The punishment of *arson* was death by our ancient laws and by the Gothic constitutions; and in the Statute of the First *incendiariorum* were burnt to death. Stat. 6 Hen. VI. c. 6. made the wilful burning of a house, under special circumstances, high treason; but it was reduced to felony by the general acts of Edward the sixth and queen Mary. This offence was denied the benefit of clergy by 21 Hen. VIII. c. 1. which statute was repealed by 1 Edw. VI. c. 12; and arson was held to be out of clergy, with respect to the principal, by inference from the stat. 4 and 5 P. and M. c. 4. which expressly denied it to the accessory; though now it is expressly denied to the principal also, by 9 Geo. I. c. 22. See **BLACK-ST.** See also **PERJURY**.

INCENSE, from *incensum*, *q. d. burnt*; as taking the effect from the thing itself; an aromatic, odorous resin; otherwise called **FRANKINCENSE**.

INCEPTIVE, a word used by Dr. Wallis to express such moments, or first principles, which, though of no magnitude themselves, are yet capable of producing such as are. See **INFINITE**, and **INDIVISIBLE**.

Thus a point has no magnitude itself, but is *inceptive* of a line which it produces by its motion. So a line, though it

it have no breadth, is yet *incipient* of breadths that is, it is capable, by its motion, of producing a surface which has breadth, &c.

INCERATION, among *Apothecaries*, the mixing of liquids with something that is dry, by a gentle soaking, till the composition be brought to a substance of the consistence of soft wax.

INCERTAINTY, in Law, is that which opposeth certainty; where a thing is so ambiguously set down, that the plain meaning cannot be understood: and this is said to be the mother of contention. The questions of uncertainty arise sometimes on matter of record, as writs, counts, pleas, verdicts, &c. and sometimes on deeds or writings, or upon contracts, &c. *2 Rep. 121. Plowd. 25.* In law proceedings, uncertainty will make them void; for all proceedings in law are to be certain and affirmative; but the defendant may be at a certainty as to what he should answer, &c. *Plowd. 84.* If the court and verdict in an appeal be uncertain, there can be no judgment given thereon; and it is the same on an indictment. *3 Mod. 121.* *Uncertainty* in wills renders them void; but sometimes a term for years granted by will, may be made certain by reference to certainty; and *uncertainty* may be reduced to certainty by matter, *ex post facto*, implication, &c. *Plowd. 6. 273. 6 Rep. 20.* If there are two men of one name, and a devise of lands, &c. is to one of that name, without any distinction, it will be void for uncertainty; though perhaps an averment may make it good. *2 Bullfinch, 180.* *Uncertainty* in declarations of uses, of fines, of lands, &c. is rejected in law; for otherwise there would be no certain inheritances. *9 Rep.*

INCEST, the crime of venereal commerce between persons who are related in a degree prohibited marriage by the laws of the country.

Some are of opinion, that marriage ought to be permitted between kinsfolks, to the end that the affection, so necessary in marriage, might be heightened by this double tie; and yet the rules of the church have formerly extended this prohibition even to the seventh degree, but time has now brought it down to the third or fourth degree. See MARRIAGE.

Most nations look on incest with horror, Persia and Egypt alone excepted. In the history of the ancient Kings of those countries we meet with instances of the brother's marrying the sister: the reason was, because they thought it too mean to join in alliance with their own subjects; and still more so, to have married into the families of any foreign prince. As to the Persians, there was a still more abominable sort of incest practised by their magi: if we may trust Catalani, *turn. 91.*

*Nam magus ex matre sed quatuor signatur species,
Si vasa est Persarum impia religio.*

In 1650, incest and wilful ADULTERY were made capital crimes; but at the Restoration it was not thought proper to renew a law of such unfashionable rigour; and these offences have been ever since left to the feeble coercion of the spiritual court, according to the rules of the canon law.

Spiritual Incest, is the like crime committed between two persons who have a spiritual alliance, by means of baptism, or confirmation.

Spiritual Incest is also understood of a vicar, or other beneficiary, who enjoys both the mother and the daughter; that is, holds two benefices, the one whereof depends on the collation of the other.

Such a spiritual incest renders both the one and the other of those benefices void.

INCESTUOUS, the name of a sect or heresy, which arose in Italy about the year 1065.

The heresy of the *Incestuosus* had its beginning at Ravenna; the leaders of which place, being consulted by the Florentines about the degrees of affinity which prohibit marriage, made answer, that the seventh generation, mentioned in the canon, was to be taken on both sides together: so that four generations were to be reckoned on one side, and three on the other.

They proved this their opinion by a passage in Justinian's Institutes, where it is said, that a man may marry his brother's, or sister's grand-daughter, though he be but in the fourth degree; whence they concluded, that if my brother's grand-child be in the fourth degree with respect to me, she is in the fifth with respect to my son, in the sixth with respect to my grandson, and in the seventh with respect to my great-grandson.

Petrus Damian wrote against this opinion, and pope Alexander II. condemned it in a council held at Rome.

INCH, a known English measure, the twelfth part of a foot.

INCH of candle, a manner of selling goods among merchants. The method of it is thus.—Notice is usually given upon

Vol. II. No. 184.

the Exchange in writing and elsewhere, when the sale is to begin: against which time the goods are divided into several parcels, called *lots*, and papers printed of the quantity of each, and of the conditions of sale; as, that none should bid less than a certain sum more than another had bid before. During the time of the bidding, a small piece, of about an inch, of wax-candle, is burning; and the last bidder, when the candle goes out, has the lot or parcel exposed to sale.

INCHASING, in Sculpture. See ENCHASING.

INCHOATIVE, a term signifying the beginning of a thing, or action; the same with what is otherwise called *incipit*.

INCHOATIVE verbs, denote, according to Priscian and other grammarians, verbs that are characterized by the termination *eo* or *fer*, added to their primitives: as *exco* from *augere*, *exco* from *calere*, *exco* from *dulcere*, *exco* from *irasci*, &c.

INCIDE, cut.—Those medicines are said to *incide*, which consist of pointed, and sharp particles: as acids, and moist salts; by the force or insinuation of which the particles of other bodies, which before cohered, are divided from one another.

And thus some expectorating medicines are said to *incide*, or cut the phlegm, when they break it, so as to occasion its discharge. See EXPECTORATION.

INCIDENCE, in Mechanics, expresses the direction in which one body strikes on another, otherwise called *incination*.

In the incursions of two moving bodies, their incidence is said to be perpendicular or oblique, as their directions or lines of motion make a right line, or an oblique angle at the point of contact.

Angle of incidence, commonly denotes the angle comprehended between an incident ray, or other body, and a perpendicular to the plane in the point of incidence.

Thus supposing AB (Tab. II. Optics, fig. 26.) an incident ray proceeding from the radiant point A, to B the point of incidence, and HB a perpendicular to DE in the point of incidence: the angle ABH, comprehended between AB and HB, is the angle of incidence, by others called the angle of inclination.

Angle of incidence is also used by Dr. Barrow, and some others, for the complement of the above angle, or of the angle of inclination.

Thus, supposing AB an incident ray, and HB a perpendicular, as before; the angle ABD comprehended between it and the reflecting or refracting plane DE, is the angle of incidence; and the angle ABH, the angle of inclination.

Others, with Wolfius, make another distinction; which see under the articles ANGLE, REFLECTION, and REFRACTION.

It is demonstrated by optical writers, 1^o, That the angle of incidence, ABH, fig. 26, is always equal to the angle of reflection HBC, or the angle ABD to the angle CBE, and they lie in the same plane. See REFLECTION.

2^o, That the sines of the angles of incidence and refraction are to each other accurately, or very nearly in a given ratio. See REFRACTION.

3^o, That from air to glass the sine of the angle of incidence is to the sine of the refracted angle as 300 to 193, or nearly as 24 to 9: on the contrary, that from glass to air, the sine of the angle of incidence, is to the sine of the refracted angle as 193 to 300, or as 9 to 24. See REFRACTION.

It is true, Sir Isaac Newton having shewn, that the rays of light are not all equally refrangible, there can be no precise ratio fixed between the sines of the angles of refraction and incidence; but the proportion which comes nearest, is that above specified. See LIGHT, COLOUR, REFRACTION, &c.

INCIDENCE of eclipses. See ECLIPSE and IMMERSION.

Axis of incidence. See AXIS of incidence. Such is the line BH, fig. 26.

Cathetus of incidence. See CATHETUS of incidence; see also REFLECTION.

Line of incidence, in Catoptrics, denotes a right line, as AB, Tab. II. Optics, fig. 26, whereby light is propagated from a radiant point A, to a point B, in the surface of a speculum.—This is also called an incident ray.

Line of incidence, in Dioptrics, is a right line, as AB, Tab. IV. fig. 56, whereby light is propagated unrefracted, in the same medium, from the radiant point to the surface of the refracting body HKLI.

Point of incidence, is the point B on the surface of the reflecting or refracting medium, in fig. 26, and fig. 56, on which the incident ray falls.

Serpio of incidence. See SERPENS.

INCIDENT, in a general sense, denotes an event, or a particular circumstance of some event.

INCIDENT, in Law, is a thing appertaining to, or following

ing another, that is more worthy or principal. A comparison is inferably incident to a minor; and a court of pie-powders to a fair.

INCIDENTS, in the *Materia Medica*. See **ATTENDANTS**.

INCIDENT, in a *Poem*, is an episode, or particular action, joined to the principal action, or depending on it.

A good comedy is to be full of agreeable incidents, which divert the spectators, and form the intrigue. The poet ought always to make choice of such incidents as are susceptible of sentiment suitable to the nature of his poem. The variety of incidents well conducted makes the beauty of an heroic poem, which ought always to take in a certain number of incidents to suspend the catastrophe, that would otherwise break out too soon.

INCIDENT *ray*. See **RAY**, **INCIDENCE**, and **INCLINATION**.

INCINERATED salts, the same with **FIXED salts**. See the following article, and **LIXIVIAL**.

INCINERATION, derived from *in*, and *cinis*, ashes, in *Chemistry*, the reduction of vegetables into ashes, by burning them gently.

This term is *occasionally* used for the making of glass.

INCISION *crucial*. See **CRUCIAL**.

INCISION, *grafting by*. See **INGRAFTING**.

INCISIVE, *Incisivus*, in *Anatomy*, is applied to several teeth, a double muckle, and certain canines situated near those teeth.

INCISIVE *arteries*. See **CUTTING TERTH**.

INCISIVUS is also an appellation given to the first proper muscle of the upper lip, because it has its origin in the bone of the upper jaw, near the place of the *maxillary* teeth; hence it pulls, and is inserted into the upper lip, which it serves to draw up. The maxillary bones have four internal orifices, two without are called *incisive*, as being directly under the *dentis incisivi*.

INCISORIUS *musculus*, in *Anatomy*, a name given by Santorini to the muscle called by *Albucius* *levator labii inferioris* and *levator labii inferrioris*, by Cowper. See the preceding article. Of these muscles, called *incisivi*, or *incisivi*, there are the *inferiores* *Cowperi*, which arise from the alveoli of the lateral *incisivi* of the lower jaw, and are inserted into the middle of the *semicircularis* of the lower lip. There are also the *incisivi laterales*, which are a sort of *triceps* muscles, uniting into one at their lower end; they arise from the os maxillare, below the middle tendon of the orbicularis palpebrarum, and below the edge of the orbit in the os maxillare, near the union of this bone with the os male. Their two portions, on each side, unite about the lateral cutting terti. The *incisivi medii*, called also the *incisivi medii* of Cowper, or better upper *incisivi*, are two small short muscles, situated near each other, below the septum maxillare; they rise from the os maxillare, on the alveoli of the first incisores, and are inserted into the middle and upper part of the upper lip.

INCLAVE, in *Heraldry*, a term used by Morgan to express an irregular line in heraldry, differing from the indented, invected, and the others. It is called by some pines, and by others the dovetail line, from its resemblance to that joint, known among our joiners by this name. It is also called by some the labelled line. It has these names from the figure of the points, as they proceed from the ordinary, such as a chaf or tails resembling the ends of labels.

INCLINATION, in *Medicine* and *Chemistry*, the operation of pouring of a clear liquor from some vessel, or sediment, by only gently sloping the vessel.

This amounts to the same with what is otherwise called **DECANTATION**.

INCLINATION, in *Physics*, expresses the mutual approach or tendency of two bodies, lines, or planes, towards one another; so that their directions make at the point of contact an angle of a greater or lesser magnitude.

INCLINATION of a right line in a plane, is the acute angle, which such a right line makes with another right line drawn in the plane through the point where the inclined line intersects it, and through the point where it is also cut by a perpendicular drawn from any point of the inclined line.

INCLINATION of a straight line, in *Dialling*, the angle that the hour-line, on the globe, which is perpendicular to the dial plane, makes with the meridian.

INCLINATION of an incident ray, otherwise called the *angle of incidence*. See **ANGLE OF INCIDENCE**.

INCLINATION of a reflected ray, is the angle which a ray after reflection makes with the axis of inclination.

Thus, if *AB* *Tab. II. Opt. fig. 18*, be the incident ray, *HB* perpendicular to *DE* in the point *B*, and *BC* the reflected ray, *CBE* will be the inclination of the reflected ray, and *ABH* the inclination of the incident ray.

INCLINATION of the axis of the earth, is the angle which it makes with the plane of the ecliptic; or the angle between the planes of the equator and ecliptic.

INCLINATION of the magnetic needle. See **DIREC.**

INCLINATION of a planet, is an arch or angle comprehended between the ecliptic, and the place of a planet in his orbit.

The greatest inclination of Saturn, according to Kepler, is $2^{\circ} 32'$ of Jupiter $1^{\circ} 20'$ of Mars $1^{\circ} 30'$ of Venus $3^{\circ} 21'$ of Mercury $6^{\circ} 55'$. According to de la Hire, the greatest declination of Saturn is $1^{\circ} 33'$ of Jupiter $1^{\circ} 19'$ of Mars $1^{\circ} 51'$ of Venus $3^{\circ} 23'$ of Mercury $6^{\circ} 52'$ of. See **JUPITER**, **MARS**, **MERCURY**, &c.

INCLINATION of a plane, in *Dialling*, is the arch of a vertical circle, perpendicular both to the plane and the horizon, and intercepted between them.

To find this, take a quadrant, and apply its side to the side of a square, and apply the other side of your square to your plane: if the plummet fall parallel to the side of the square, then the lower side of the square stands level; by which draw an horizontal line, whereon erect a perpendicular, and apply your square to that perpendicular; and if the plummet falls parallel to the side of the square, then that is also a level line, and your plane stands horizontally: if the plummet falls not parallel to the side of the square, then turn your square, until it does; and draw an horizontal line, on which erect a perpendicular, to which apply your square, and observe what angle your plummet makes on the quadrant, with the side of the square: that is the angle of the inclination of the plane. See **DECLINATION**.

INCLINATION of two planes, is the acute angle made by two lines drawn one in each plane, through a common point of section, and perpendicular to the line common section.

Thus, in *Tab. III. Geometry, fig. 51*, the inclination of the plane *KEGL* to the plane *ACDR*, is the angle *HEI*, made by the right lines *HE* and *FI* in the point *E*, perpendicular to the line of section *EL*.

INCLINATION, angle of, in *Optics*, is the same with what is otherwise called the *angle of incidence*.

INCLINATION, argument of. See **ARGUMENT**.

INCLINATION, in a moral sense. See **APPEHIVE**.

INCLINED plane, in *Astronomy*. See **INCLINED PLANE**.

See also **MECHANICS**, and **MECHANICAL POWERS**.

INCLINED towers. See **TOWERS**.

INCLINERS, in *Dialling*. See **DIAL**, and **DECLINERS**.

INCLOSING of land. See **LAND**.

INCOGNITO, a term borrowed from the Italians, used when a person is in any place where he would not be known; but it is more particularly applied to princes, or great men, who enter towns, or walk the streets, without their ordinary train, or the usual marks of their distinction and quality; or when they travel without their proper titles.

The grandees in Italy make a common custom of wearing the *fracca incognita*, and always take it off, on some occasion, when they pay their compliments to a king. It is not hard to prevent their being known, that is, to take these measures; but because they would not be treated with ceremony, nor receive the honours due to their rank.

When the horses in princes, cardinals, and ambassadors coaches have no tails, which they call *fracca*, and the carriages, which they call *banderole*, are drawn, they are reputed to be *incogniti*; and nobody that meets them is obliged to stop, or make his honours to them.

The cardinals also, when they would be *incogniti*, leave off the red hat.

INCOMBUSTIBLE, that which cannot be burnt or consumed by fire.

Metals melt, stones calcine, and are yet *incumbustible*. Cloth made of *lepis amianthus* has been deemed *incumbustible*; it is cleaned by fire, but not burnt.

INCOMBUSTIBLE, in *Chemistry*, is a name given by authors to a particular kind of asphalt, or earth flux, which never is dissolved into compact masses as the other species are, but is always found in loose filaments, and those of a very flexible nature, and extremely fit to work.

This is a kind of asphalt, wholly different from the species known to the ancients, and is found, so far as is yet known, only in the county of Aberdeen in Scotland, in the neighbourhood of Abertree, near the Highlands.

See **ASPHALTUM**, and **LINUM INCOMBUSTIBILE**.

The fabricating a cloth of this substance has not yet been attempted; but Mr. Wilson, who first discovered it, had some of it spun into yarn, which gives proof that the other is practicable. Phil. Trans. N^o 276. p. 2005.

INCOMMENSURABLE, a term in geometry, used where two lines, when compared to each other, have no common measure, how small soever, that will exactly measure them both.

In the general, two quantities are said to be *incommensurable*, when no third quantity can be found that is an aliquot part of both; or, when those quantities are not to one another as unity to a rational number, or, as one rational number to another. See COMMENSURABLE.

The side of a square is *incommensurable* to the diagonal, as is demonstrated by Euclid; but it is commensurable in power, the square of the diagonal being equal to twice the square of the side.

Pappus, lib. ix. prob. 17. speaks also of *incommensurable* angles. Surfaces which cannot be measured by a common surface, are also said to be *incommensurable* in power. See DIOPHANTINE problems.

INCOMPATIBLE, that which cannot subsist with another without destroying it.

Thus cold and heat are *incompatible* in the same subject; the strongest overcoming and expelling the weaker.

INCOMPARABLE degrees, in Law, are those which cannot be retained together, if they be with care, and of a particular value in the king's books. See CHAPLAIN.

INCOMPLEX species. See OPPOSITION.

IMPOSIBLE numbers are the same with what Euclid calls *penny numbers*. See PENSE and NUMBER.

INCONCINNOUS discord. See DISCORD.

INCONCINNUS fetus. See SYSTEM.

INCONTINENCE. Beside the moral sense of this word, it signifies in medicine an inability in any of the organs to retain what should not be discharged without the concurrence of the will. But *incontinence* is most frequently used with regard to an involuntary discharge of urine.

The bladder is sometimes so debilitated in men, that their urine flows from them involuntarily, by drops, not exceeding the usual quantity; which may proceed either from a stone in the bladder, or a palsy of the sphincter, or injuries occasioned by blows, bruises, &c. Sometimes this is the effect of a fever; and it may be likewise occasioned by a long use of *laxing* diuretics, or of stimulating medicines, injected into the bladder. In the first case the only remedy is lithotomy, or an extraction of the stone; nor is lithotomy infallible; for that operation frequently occasions the disorder. But if it proceeds from a weakness in the neck of the bladder, astringent and corroborating medicines are most likely to remove or to diminish it. See DIABETES.

But as this disorder often baffles the utmost power of medicines, the surgeons have contrived instruments to retain the urine. Some recommend a leathern bag lined with pitch, to be worn in the breeches between the thighs, large enough to contain half a pint; others prefer a brass or a steel pipe, fastened to the penis, to be emptied when near full. But as these are very inconvenient, the moderns have contrived more light and easy instruments, whereby the penis and urethra are gently compressed, so as to retain the urine in the bladder, and discharge it at pleasure, by opening and shutting this light instrument, which is lined with leather, and taken from Nuck. Another still more convenient may be tightened or relaxed, according to the different size of the penis. This Heister says he has often used with success; nor was it ever before delineated by any one.

An instrument was formerly recommended by Nuck, and lately by Winslow, for this disorder; not unlike that used for ruptures. It is to be fastened round the body in the manner directed for compressing fistulas in the perineum; so that the bolster may be fixed tight upon the perineum. Thus, by turning a screw, the urethra may be compressed or relaxed, and the urine discharged or retained at pleasure.

An *incontinence* of urine in women frequently proceeds from a difficult labour, or from a weakness of the sphincter, by the violent extraction of a large stone; though it sometimes happens from a natural weakness or palsy, as in men. But whatever the cause may be, when it is inveterate, or proceeds from the palsy, it will neither submit to internal medicines, nor external machines.

If however it arises from the extraction of a stone, especially in girls or young women, it often goes off spontaneously, or by the external or internal use of astringents; if it does fall, it is generally looked upon as incurable. Hirschers affirms, however, in a treatise upon this subject, that the best method is to introduce a pessary, or ring of proper size, into the vagina; as for a prolapsus uteri: for the introduction of this into the vagina, under the urethra, compresses the latter so firmly, that the urine may be retained or discharged at pleasure. James. See *Incontinence of URINE*.

INCONTINENCY, in a moral sense, is of divers kinds; as in cases of bigamy, rapae, sodomy, or boggery, getting bastards; all which are punished by statute. See 2 Hen. VIII. cap. 6. 18 Eliz. cap. 7. 1 Jac. I. cap. 11. *Incontinency* of priests is punishable by the ordinary, by imprisonment, &c. 1 Hen. VII. cap. 4.

INCORPORATION, formed from *in*, and *corpus*, *body*, the mixing the particles of different bodies together, as to make an uniform substance or composition of the whole, without leaving any possibility of discerning the ingredients or bodies mixed, in any of their particular qualities.

INCORPORATION, in Law. See CORPORATION.

INCORPOREAL, *spiritual*, a thing, or substance, which has no body. See SPIRIT, and BODY.

Thus the soul of man is *incorporeal*, and may subsist independent of the body. See SOUL.

Those ideas which are independent of bodies, can neither be corporeal themselves, nor be received within a corporeal subject; they discover to us the nature of the soul, which receives within itself what is *incorporeal*, and receives it in a corporeal manner too; whence it is, that we have *incorporeal* ideas even of bodies themselves. Fenelon.

INCORPOREAL inheritance, in Law. See INHERITANCE.

INCORRUPTIBLE, that which cannot be corrupted. See CORRUPTION.

Thus spiritual substances, as angels, human souls, &c. and thus also glass, gold, mercury, &c. may be called *incorruptible*.

INCORRUPTIBLES, **INCORRUPTIBILES**, the name of a sect which sprang out of the Eusebians.

Their distinguishing tenet was, that the body of Jesus Christ was *incorruptible*; by which they meant, that after and from the time wherein he was formed in the womb of his holy mother, he was not susceptible of any change or alteration; not even of any natural and innocent passions, as of hunger, thirst, &c. so that he eat without any occasion, before his death, as well as after his resurrection. And hence it was that they took their name.

INCRASSATING, the act of condensing, or rendering fluids thicker, by the mixture of other less fluid particles; or by expelling the finer particles, and compacting and bringing the grosser matter together.

Incrassating medicines are such as reduce the too fluid blood and juices to a proper consistence.

INCREMENT, *Incrementum*, in Kibiers, a species of climate, gradually rising from the lowest to the highest. Such is that of Seneca's *Turpissima tempestas est, quae per neglectum venit, et si adverti attendere, magna vires parit, stabilius multo aequabitur, maxima nihil aequabitur, tota aliud agens*. See CLIMAX.

INCROACHMENT, in Law. See ENCROACHING.

INCUSTATION, the lining or coating of a wall, either with glossy stones, rustics, marble, pottery, or stucco-work; and that either equally, or in panels and compartments.

INCUSIED, or **INCUSTATED column**. See *Incrustated Column*.

INCUBATION, the action of a hen, or other fowl, brooding on her eggs.

INCUBUS, *night-mare*, in Medicine, a disease consisting in the spasmodic contraction of the muscles of the breast, so very violent, that the patient cannot speak or even breathe.

The word is derived from the Latin *incubare*, *to lie down on any thing*, and *propiis*. The Greeks called it *incubus*, q. d. *salutis, lepro*, or something that rusteth on a person.

In this disease the senses are not quite lost, but they are drowned and astonished, as is also the understanding and imagination; so that the patient seems to think some huge weight thrown on him, and ready to strangle him. Children are very liable to this distemper; so are fat people, and men of much rust and application of mind; because the stomach, in all these, finds some difficulty in digestion.

The *incubus* seems to be nearly allied to the epilepsy and apoplexy; for, if it lasts long, it degenerates into one or other of those distempers. Others reckon it a kind of asthma, and call it *asthma nocturnum*; and say it proceeds from the same causes, and is helped by the same means as the common asthma.

Signs of it. The most obvious symptom of this disease is a sensation like that of some great weight laid upon the breast; this is attended with so violent a prohibition of respiration, that the person becomes unable to move any part of his body, or to utter any distinct or articulate sound; though he sometimes groans and cries out. He sometimes imagines that he is in imminent danger of various kinds, and unable to escape. This whole complaint goes off as soon as any one limb is moved, but there is often an universal latitudo of the whole body left behind it, which remains for some space of time. This disease generally attacks people in the night-time, in a sort of middle state between sleep and waking. *Persons subject to it*. Those of plethoric habits are most

subject

fuldest to fall into this distaste, and among them such particularly as have a great thickness of the blood. Persons who are subject to hypochondriac complaints, and to disorders of the spleen, are also much affected with it, and it is usually brought on by eating large suppers, going to bed soon after, and then sleeping upon the back. *Causes of it.* There is a stagnation of the blood in plethoric habit, where it is thick about the vena portæ, which nature is endeavouring to throw off by means of those spasmodic motions which constitute this distaste; and very often cruditie in the prime viæ become additional causes, and exacerbate the complaint. Some have supposed that this disorder proceeds from a stagnation of the blood in the brain, lungs, &c. but it is rather a nervous affection, and arises chiefly from indigestion. Accordingly, persons of weak nerves, who lead a sedentary life, and live full, are most commonly afflicted with it. The disorder is often caused by wind, and by any kind of mental oppression.

Prognosis of it. This is usually esteemed a trifling complaint, and at the utmost, if it does not go off of itself, to be cured by bleeding. Physicians esteem it a distaste of no danger; but it is much to be suspected, that many of those people who are found dead in their beds perish by it.

Method of cure. When this distemper returns frequently, the method is to give gentle purges three or four times, with the digestive medicines, such as gum ammoniacum, or the tartarum vitriolatum, on the intermediate days; after this bleeding in the foot is proper; and when this has been done, powders of nitre and camphor usually complete the cure: if they fail, the common method in hypochondriac cases is to be used. When there are cruditie in the prime viæ, which exacerbate this distaste, then after the purges, gentle bitters, and other medicines which will restore the tone of the stomach, are to be given. Grenian and orange peel in infusion, are very good for this purpose. When it happens almost wholly from a load on the stomach, a gentle vomit alone will perform a cure. To prevent returns, the patients must accustom themselves to lie on one or the other side, never on the back.

Dr. Whist recommends a glass of brandy at bed-time, as a preventive; this however will gradually lose its effect, and in by no means advisable. The patient should rather depend on the use of food of easy digestion, cheerfulness, exercise in the day, and a light early supper. Persons who are young, and full of blood, if troubled with this disorder, should take a purge often, and use a spare diet. Junker and Barlaam.

INCUMBENT, in *Law*, a clerk resident on his benefice, with cure.

He is called incumbent of such church, because he ought to bend his whole body to discharge his cure. See *Rector*.

INCUMBRANCE, in *Law*, See *QUARE INCUMBRANCE*.

INCURVATION, the act of bending a bone, or other body, from its natural shape.

INCURVATION of the rays of light. See *LIGHT*, and *REFRACTION*.

INCUS, in *Anatomy*, the second of the ossicles, or little bones of the ear.

The great or malleus contained in the barrel of the ear, resembles in some measure one of the anterior grinders, with its root at a great distance from each other; at least it comes nearer to this than to the shape of an anvil. Anatomists divide it into the body, and the branches; the body is a somewhat large substance; the branches or legs are two, one long and one short; the body is turned forward, the short leg backward, and the long leg downward. The body of the *incus* is broader than it is thick; it has two eminences, and two cavities between them, much as we see in the crown of the first grinders. The short leg is thick at its origin, and from thence decreasing gradually it ends in a point; it is frusted horizontally, its point being turned backward, and joined to the edge of a malleolus opening of the tympanum. The long leg viewed through the external auditory passage appears to be situated vertically; but if we look upon it either on the face or back-side we see it is inclined, the extremity of it being turned much more inward than the root or origin. The point of the extremity is a little flatted, and bent back like a hook, and sometimes a little hollowed like a kind of ear-picker. By this the *incus* of one ear may be distinguished from that of the other, when out of their places; for turning the short leg backward and the long leg downward, if the curvature of this long leg be toward the left hand, the bone belongs to the right ear; if toward the right it belongs to the left ear. Winslow. See *EAR*.

INDECIMABLE, *Indecimabilis*, in *Law*, is applied to things not tythable, or which by law ought not to pay *TITHES*.

INDEFESIBLE, or **INDEFEASIBLE**, in our *Law*, signifies what cannot be defeated, or made void. As, a good and indefeasible estate.

INDEFINITE, *Indeterminatus*, that which has no certain bounds, or to which the human mind cannot affix any. Descartes uses the word, in his philosophy, instead of *infinite*, both in numbers and quantities, to signify an *inconceivable* number, or number so great, that an unit cannot be added to it; and a quantity so great, as not to be capable of any addition.

Thus, he says, the stars, visible and invisible, are in number *indefinite*; and not, as the ancients held, *infinite*; and that quantity may be divided into an *indefinite* number of parts, not an infinite number.

INDEFINITE is also used, in the *Schools*, to signify a line that has but one extreme: for instance, a line extended from any point, and extended infinitely.

Thus what they call *curvæ a parte unius*, or *eternæ a parte pæ*, are *indefinite* durations.

INDEFINITE, in *Grammar*, is understood of nouns, pronouns, verbs, participles, articles, &c. which are left in an uncertain indeterminate sense, and not fixed to any particular time, thing, or other circumstance.

INDEFINITE proposition, in *Logic*. See *PROPOSITION*.

INDELIBILE, formed from *indere*, to bind, with the preposition *in*, taken negatively, that which cannot be blotting out, or effaced.

Thus baptism, and the order of the priesthood, are said to convey *indelibile* characters.

INDEMNITY, formed from the negative *in*, and *damnum*, loss; in *Law*, an act by which one promises to guarantee, or save harmless, some other person from any loss or damage that might accrue to him on any particular account.

When a church is appropriated to an abbey, or college, the archdeacon bestows his induction money for ever; in recompence whereof he shall have yearly, out of the church for appropriate, one or two shillings, more or less, for a pension, as was agreed at the time of the appropriation; and this pension is called an *indemnity*.

INDEMNITY, with regard to estates. See *WARRANTY*.

INDEMNITY. See *Act of Grace*.

INDENTED, **INDENTED**, in *Heraldry*, is when the outline of a bordure, ordinary, &c. is notched, in form of the teeth of a saw. Tab. II. *Heraldry*, fig. 69.

INDENTED half. See *Gravel LIKES*.

INDENTED line, in *Fortification*. See *RIENET*.

INDENTED verge. See *DETTED*.

INDENTED medals and tokens. See *MEDALS* and *WHOLE*.

INDENTURE, in *Law*, a writing which compiles some contract between two, at least; being indented at top answerable to another part, which has the same contents. See *DEED*.

INDEPENDENT company and troop. See *COMPANY* and *TROOP*.

INDEPENDENTS, a sect of protestants in England, and Holland; so called, as denying not only any subordination among their clergy, but also all dependency on any other assembly.

They maintain, that every separate church, or particular congregation, has in itself radically and essentially everything necessary for its own government; that it has ecclesiastical power and jurisdiction; and is not at all subject to other churches, or their deputies, nor to their assemblies, or synods.

Robinson, the founder of the sect, makes express use of this term in explaining his doctrine relating to ecclesiastical government: *Cæcum quælibet particularem* (says he, in his Apologia, cap. V. p. 22.) *esse totum, integrum et perfectum ecclesiam ex suis partibus constitutam, immutabilem et independentem (quod alias ecclesiam) sub ipsi Christiani*. It may probably have been from this very passage that the title of *Independents* was originally derived. The disciples of Robinson, originally called *Brownists*, because John Robinson, the founder of this sect, was pastor of a congregation of Brownists that had settled at *Exeter*, did not reject the appellation of *Independents*. It was certainly utterly unknown in England before the year 1640; at least it is not once mentioned in the ecclesiastical canon and constitutions that were drawn up, during that year, in the synods or visitations held by the archbishops of Canterbury, York, and other prelates, in which canons all the various sects, that then subsisted in England, are particularly mentioned. See *Wilkins's Concilia Magnæ Britannicæ et Hibernicæ*, vol. iv. cap. 5. p. 528.

It is true, that not long after this period, and more particularly from the year 1642, we find this denomination very frequently in the English annals. The English *Independents* were so far from being displeased with it, that they assumed it publicly in a piece, which they published in their own defence at London, in the year 1644, entitled,

itled, Apologetical Narration of the *Independents*. But in process of time, in order to avoid the odium of sedition and anarchy charged on this sect, the true and genuine *Independents* renounced this title, and called themselves *Congregational Brethren*, and their religious assemblies *congregational churches*. The first *Independents*, or congregational church in England, was set up in the year 1606, by Mr. Jacob, who had adopted the religious sentiments of Robinson. The *Independents*, though sprung originally from a congregation of Brownists, were much more commendable than the latter, both in the moderation of their sentiments, and the order of their discipline. The Brownists, as we have already mentioned under that article, allowed all ranks and orders of men promiscuously to teach in public, and to perform the other pastoral functions; whereas the *Independents* had, and still have, a certain number of ministers, for the most part regularly educated, chosen respectively by the congregations where they are fixed; not is any person among them permitted to speak in public, before he has submitted to a proper examination of his capacity and talents, and been approved of by the congregation to which he ministers. The charge alleged against them by our historian Rapin, (*Hist. of England*, vol. ii. p. 514. fol. ed.) who says, that they could not so much as endure ordinary ministers in the church, &c. is, therefore, evidently false and groundless. He was led into his mistake by confounding the *Independents* and Brownists. There are other charges, no less unjustifiable, that have been urged against the *Independents*, by this celebrated historian, and others of less note. Rapin says, that, with regard to the state, they abhorred monarchy, and approved only a republican government. This might have been true with regard to several persons among the *Independents*, in common with those of other sects; but it does not appear from any of their public writings, that republican principles formed the distinguishing characteristic of this sect. On the contrary, in a public memorial drawn up by them in 1647, they declare, that they do not disapprove of any form of civil government, but do freely acknowledge, that a kingly government, bounded by just and wholesome laws, is both allowed by God, and also a good accommodation unto men. The *Independents*, however, have been generally distinguished by the denomination of *regicides*; under a notion, that they were chargeable with the death of Charles I. Whether this fact be admitted or denied, and this is not a place proper for the investigation of it, no conclusion can be fairly drawn from the greater prevalence of republican principles, or from violent proceedings at that period, that can affect the distinguishing tenets and conduct of the *Independents* in general; and especially of the sect that bears this denomination in our times. It is certain, that our *Independents* are steady friends to a limited monarchy. Rapin is farther mistaken, when he represents the religious principles of the *Independents* as contrary to those of all the rest of the world. It appears from two confessions of faith, one composed by Robinson, on behalf of the English *Independents* in Holland, and published at Leyden in 1619, intitled, *Apologia pro exulibus Angliæ*, qui Brownistæ vulgo appellantur, and another drawn up in London in the year 1658, by the principal members of this community in England, entitled, *A Declaration of the Faith and Order owned and practised by the Congregational Churches in England*, agreed upon and consented unto by their Elders and Messengers, in their Meeting at the Savoy, O.C. 12, 1658; as well as from other writings of the *Independents*, that they differed from the rest of the reformed in no single point of any consequence, except that of ecclesiastical government; and their religious doctrines were almost entirely the same with those that are adopted by the church of Geneva. During the administration of Cromwell, the *Independents* acquired very considerable reputation and influence; and he made use of them as a check to the ambition of the Presbyterians, who aimed at a very high degree of ecclesiastical power, and who had succeeded, soon after the elevation of Cromwell, in obtaining a parliamentary establishment of their own church government. But after the restoration of Charles II. their cause declined; and in the year 1693, under the reign of king William, they entered into an association with the Presbyterians residing in and about London, under certain heads of agreement, comprized in nine articles, that tended to the maintenance of their respective institutions. These may be found in the second volume of Whiston's *Memoirs of his Life and Writings*; and the substance of them in Moheim, *ubi infra*. At this time the *Independents* and Presbyterians, called from this association the United Brethren, were agreed with regard to doctrines, being generally Calvinists, and differed only with respect to ecclesiastical discipline. But

at present, though the English *Independents* and Presbyterians form two distinct parties of protestant dissenters, they are distinguished by very trifling differences with regard to church government; and the denominations are more arbitrarily used to comprehend those who differ in theological opinions. The *Independents* are generally more attached to the tenets distinguished by the term *ORTHODOXY* or *CALVINISM*, than the *PRESBYTERIANS*.

Independence is peculiar to Great Britain, the British colonies of America, whither it was carried first in 1625, and by successive Puritan emigrants in 1629 and 1633, from England and the United Provinces. One Morel, in the sixteenth century, endeavoured to introduce it into France; but it was condemned at the synod of Rochel, where Beza presided; and again at the synod of Rochel, in 1644.

On the subject of this article, see Moheim's *Ecc. Hist.* by Maclean, vol. iv. p. 522, &c. Rev. Neal's *Hist. of the Puritans*, vol. ii. p. 107, &c. vol. iii. p. 547, &c. vol. iv. p. 187, &c. Burnet's *Hist. of his Own Times*, vol. i. p. 46, &c.

INDETERMINATE, in *Geometry*, is understood of a quantity either of time or place, which has no certain or definite bounds. See **INFINITE**.

INDETERMINATE problem, is that, whereof there may be infinite different solutions.

For instance, if a number be required that may be a multiple of 4 and 5; where the answer may be 20, 40, 60, &c. to infinity. Thus also, in a question of **ALLIGATION**, if a refiner, having three ingots of silver of different fineness, viz. of 4, 6, and 10 ounces, were required to mix a mass of 20lb weight, in as to make it 8 ounces fine; how much must he take of each sort? The best way, in this, is to determine algebraically the limits of any one of the unknown quantities: suppose them x, y, z . Then, from the premised conditions, $x+y+z=20$. And $4x+6y+10z=160$. Therefore, $x=20-y-z$. And $4(20-y-z)+6y+10z=160$. Consequently x is less than 14.

Also, $x=20-40-3z=20-2z$: therefore x is greater than 10. Whence the limits of x are 14 and 10, and we shall have the following answers in whole numbers.

x	y	z
14	7	2
12	4	4
10	1	6

Or, if it were required to find two numbers whose sum together with their product may be equal to a given number, or to make a rhomboides, wherein the rectangle under the two sides may be equal to a given square; both of these problems admit of infinite solutions. See **DIOPHANTINE problems**.

INDEX, in *Anatomy*, denotes the *fore-finger*.

It is thus called from *Indes*, *Indus*, *direct*; because that finger is generally so used: whence also the extensor indicis is called *indicator*.

The Greeks call it *xyxaris*, *finger*.

INDEX, in *Arithmetic*, is the same with what is otherwise called the *characteristic*, or *EXPONENT* of a **LOGARITHM**.

The *index* is that which shews of how many places the absolute number belonging to the logarithm consists, and of what nature it is, whether an integer, or a fraction.

Thus, in this logarithm 2,512,293, the number standing on the left hand of the point is called the *index*; and because it is 2, it shews you that the absolute number answering to it consists of three places; for it is always one more than the *index*, because the *index* of 1 is 0; of 10 it is 1; and of 100 is 2, &c. And, therefore, in those small tables of Briggs's Logarithms, where the *index* is omitted, it must be always supplied, before you can work by them.

If the absolute number be a fraction, the *index* of the logarithm has a negative sign, and is marked thus, 2,562293; which shews the corresponding number to be a decimal fraction of three places; viz. 1,365.

Mr. Townly has a peculiar way of noting these *indices*, when they express fractions, now much in use, viz. by taking, instead of the true *index*, its arithmetical complement to 10; so that he would write the logarithm now mentioned thus: 8,562293.

How *indices* are to be added and subtracted, see under the article **LOGARITHM**.

INDEX of a book, is that part annexed to a book, referring to the particular matters or passages therein contained.

INDEX of a globe, is a little style fixed on to the north-pole, and turning round with it, pointing to certain divisions in the hour-circle.

It is sometimes also called *gnomon*. See **GLOBE**.

INDEX of relation, in *Algebra*, the same with scale of relation. See **SCALE**.

INDEX, or **LYSTICK**, is also the denomination of a congregation at Rome, whose business is to examine books, and to put such as they think fit to prohibit the reading and selling of, into an *index*.

Index, in *Library*, *Index*, is the name by which the catalogues of prohibited books are called; among which, however, there is this difference, that some are condemned purely and absolutely, and others only *ad cautelam*, till they be corrected.

Father Paul says, that Philip of Spain was the first who, by a law made in 1588, procured an *index* to be published of the books condemned by the inquisition of Spain. Pope Paul IV. took the hint, and in 1559 ordered the congregation of the holy office at Rome to print a second. But Gretser, De Jure Prohib. lib. ii. cap. 19. says, that the *index* of prohibited books was printed in Italy, by the papal authority, in 1548; and a larger one, in 1551; and another larger in 1554. Pius IV. recommended the matter to the council of Trent, the fathers at Trent, after several debates, not being able to agree, though fit to refer the whole affair to the pope, when, with the advice of certain learned prelates, published an *index* of the prohibited books, and certain rules, by his letters, in form of a brief. The same Pius IV. in a bull of March 24, 1564, says, that the *index* was presented to him by order of the synod, that it should not be published before it was approved by him. It was accordingly published by him, with a strict charge that it should be received by all, and the rules prefixed to it observed. Clement VIII. enlarged and confirmed it, together with the rules, and commanded it to be published in 1595. This was called by the name of the Roman *Index*. By the fourth rule, the common reading of the Holy Scriptures is forbid in these words: "Since it is plain by experience, that if the sacred writings are permitted every where, and without difference, to be read in the vulgar tongue, men, through their rashness, will receive more harm than good; let the bishop or inquisitor determine, with the advice of the parish priest or confessor, to whom to permit the reading of the Bible, translated by catholic authors, in the vulgar tongue, according as they shall judge whether it be most likely that such reading the Scripture may do harm, or tend to the increase of faith and piety. Let them also have the same power as to all other writings. But if any, without such leave, shall presume to read or have them, without first showing the Bible to the ordinaries, he shall not receive the absolution of his sins. And as to all book-sellers, who shall sell the Bible translated into the vulgar tongue, without such leave, as by any other method shall publish them, let them forfeit the price of the books, and let the money be given to pious uses by the bishops, and let them be subject to other punishments, at the pleasure of the said bishop, according to the nature of the offence. As to regulars, they shall not read or buy them, without leave first obtained from their prelates." The tenth rule enjoins several restrictive regulations concerning the printing and publication of books. Hardouin's Council, tom. 2. p. 307, 60.

After this, the duke of Alva procured another to be printed at Antwerp, in 1571, which was published by Francis Junius about the year 1586. There were two others published in 1584, and 1612; by the cardinals Quiroga and Sanzola, and several others by the inquisitors and masters of the sacred palace. The most considerable of all the *indices* is that of Anthony a Soto-mayor, supreme president and inquisitor-general in the kingdom of Spain, which was made for all the states subject to the king of Spain, and comprehends all the others. This was published, with the advice of the supreme senate of the general inquisition, in 1640, and reprinted at Geneva in 1657. To this there were many rules prefixed; and to the Geneva edition was added the *index* of the decrees which were made by the master of the holy palace, by virtue of his office, or by the command of the holy congregation, or by the holy congregations for the *index* and holy office, after the before mentioned *index* of the council of Trent. The rules of the former *index* are explained and confirmed by these; and the fifth rule, which enlarges the fourth of the *index* of Trent, prohibits not only all Bibles in the vulgar tongue, comprehending all except those that are Hebrew, Greek, Latin, Chaldee, Syriac, Ethiopic, Persian, and Arabic; but all parts of them, either printed or manuscript, with all summaries and abridgements in the vulgar language or tongue. Limborch's Hist. of the Inquisition by Chandler, book ii. chap. 16.

Of the operation of these *indices*, the authors of the Encyclopædia observe, that there has been hardly any good

book of piety or morality in their language which has not been proscribed. Art. *Index*.

INDEX of the variation and of the inequality of curvature. See **VARIATION** of curvature.

East INDIA Company, *Coins, Silk, &c.* See **COMPANY**, **COIN**, **SILK**, &c.

INDIAN, in a general sense, denotes any thing belonging to the Indies, East or West.

INDIAN arrow-root. See **ARROW-root**.

INDIAN bread. See **CASSADA**.

INDIAN corn. See **MAIZE**.

INDIAN Crafts, *Gum, Fish, Ocean, Red*. See the respective *substantives*.

INDIAN fig, in *Botany*. See **Priestly PEAR**.

INDIAN tree, the name of a species of fig.

INDIAN leaf, *Malabathrum*. See **TAMALAPATRIS**.

INDIAN riel. See **CASH** and **REED**.

INDIAN wood, called also *Tamala* and *Camphire tree*, is taken out of the heart of a large tree growing plentifully in the files of Jamaica, Camaguey, &c. also in drying, its decoction being very red.

It has been observed, that putting some of this decoction into two bottles, and mixing a little powder of alum with the one, it will become of a very beautiful red, which will hold; the other in a day's time becoming yellow, though both bottles were stopp'd from the air alike; and that if a little of the same decoction be exposed to the air, it will become as black as ink in the same space of time. See **CAMPFACITY WOOD**, **BRAZIL**, and **LOG-WOOD**.

INDICATION, in *Physic*, signifies the pointing out or discovering what is fit to be done, and what means applied in any case, from a knowledge of the nature of the disease, and the virtue of medicines.

Indication is of four kinds; *preservative*, or *prophylactic*, which direct how to cut off the cause of an approaching disease; *curative*, which shew how to remove a disease actually formed; *palliative*, which direct how to lessen its effects, or take off some of its symptoms, before it can be wholly removed; and *vital*, which relate to the strength of the body.

That part of physic which treats of *indications* is called **TELEIOTICA**.

INDICATIVE, in *Grammar*, the first mood or manner of conjugating verbs, shewing either the time present, past, or future, and asserting what we think certain; and, therefore, sometimes called the *declarative mood*.

I live, is the present tense; *I lived*, the past; and *I will live*, is the future of the *indicative mood*.

INDICATIVE idiom. See **COLOM**.

INDICATOR, in *Anatomy*, a muscle of the **INDEX**, or finger, next following the thumb.

The *indicator* is the first proper muscle of the **index**; and is so called, because it serves to extend that finger to point at any thing.

It has its origin in the middle and hind part of the cubitus, and is inserted by a double tendon into the second phalanx of the **index**, and to the tendon of the great extensor, with which it acts in conjunction in stretching out the finger. See *Tab. Anat. (Muscl.) fig. 7. n. 10. 11.* See **EXTENSOR**.

INDICAVIT, in *Law*, a writ or prohibition that lies for a patron of a church, whose clerk is sued in the spiritual court, by another clerk for tythes, which do amount to a fourth part of the profits of the advowson; then the suit belongs to the king's court, by the stat. West. 2. cap. 5. And the patron of the defendant being likely to be prejudiced in his church and advowson, if the plaintiff recovers in the spiritual court, hath this means to remove it to the king's court: *Reg. Orig. 35. Old Nat. Br. 31.*

INDICTION, signifies the convoking of an ecclesiastical assembly; as a synod, or council, or even a diet.

INDICTION is applied to the several sessions of the ecclesiastical council.

Hence it is, that at the end of the sessions of the council of Trent, the decree by which the council appoints the day of the future session, is called the *indiction* of this session.

INDICTION, in *Chronology*, a term used for a kind of epocha, or manner of counting time among the Romans; containing a cycle or revolution of fifteen years, which, when expired, begins anew, and goes round again without intermission.

This method of computation has no dependence on the heavenly motions. Petaviana says, there is nothing in chronology less known than the Roman *indiction*; he means, that its original and commencement is. It is the general opinion, that it was instituted in the time of Constantine, about the year 312; but this is a mere guess. There were *indictiones* in the time of the emperor Constantine, as appears from the Theodosian Code. The learned hold, that *indictiones* were originally no other than certain

certain annual taxes, the tariffs whereof were published every year; but why they were so called, why confined to a cycle of fifteen years, when, and on what occasion, instituted, is not known.

We find three kinds of *indictiones* mentioned in authors: the *indictio* of Constantinople, beginning on the first of September; the Imperial, or Caesarian *indictio*, on the fourteenth of September; and the Roman, or papal *indictio*, which is that used in the pope's bulls, and which begins on the first of January.

The popes have dated their acts by the year of the *indictio*, which was fixed to the first of January, A. D. 323, ever since Charlemagne made them foreign; before which time they dated them by the years of the emperors.

At the time of the reformation of the calendar, the year 1582 was reckoned the tenth year of the *indictio*; so that beginning to reckon hence, and dividing the number of years elapsed between that time and this by 15, the remainder, with the addition of 10, will be the year of *indictio*, corresponding to the year of our Lord 1780.

The *indictio* may also be found by adding 12 to the year of our Lord, and dividing the sum by 15, the remainder is then the year of the *indictio*: if there be no remainder the *indictio* is 15. In either of these ways the year of *indictio* for 1780 is 13.

The word *indictio* comes from *indictis*, which signifies *exaltation, order, or denunciation*. The time of the *indictio*, among the Romans, was that wherein the people were summoned to pay a certain tribute; and it is for this reason, that the imperial *indictio* began towards the end of September; because the harvest being then got in, it was supposed the people could more easily pay their tax.

INDICTIVE, INDICTIVUS, an epithet given to certain feast-days appointed by the Roman magistrates, viz. the consular, or *praetor*.

INDICTMENT, derived from the French *indictre, indiquer*, or, according to M. Lambard from *indicare, I charge, I inform* *expositio*, in Law, a bill or declaration, of complaint, drawn up, in form of law, for the benefit of the commonwealth: exhibited as an accusation of one for some offence, criminal or penal, and preferred to a grand jury, and by their verdict found to be true, and presented before a judge or officer, who has power to punish or certify the same offence.

INDICTMENT, in Common Law, signifies as much as *accusatio* among the civilians; though in some points it differs. See **ACCUSATION**.

Lambard says, an *indictment* is an accusation at the suit of the king, by the oaths of twelve men of the same county where the offence was committed; returned to inquire of all offences in general in the county, determinable by the court into which they are returned, and their finding a bill brought before them to be true. But when such accusation is found by a grand jury, without any bill brought before them, and afterward reduced to a formed *indictment*, it is called a *preconception*; and when it is found by jurors returned to enquire of that particular offence only, which is indicted, it is properly called an *inquisition*.

Although a bill of *indictment* may be preferred to a grand jury upon oath, they are not bound to find the bill, if they find cause to the contrary; and though a bill of *indictment* be brought to them without oath made, they may find the bill if they see cause. But it is not usual to prefer a bill unto them, before oath be first made in court, that the evidence they are to give unto the grand inquest to prove the bill, is true.

The grand jury are to find the whole of a bill, or to reject it; and not to find it specially in part, &c. if they are justified of the truth of the accusation, they then *indorse* upon the bill of *indictment* "a true bill," anciently *VERA*. But to find a bill, there must at least twelve of the jury agree. The *indictment*, when so found, is publicly delivered into court.

As *indictments* are purely for the good and quiet of the commonwealth, they are to be preferred for criminal, not civil matters. They are used in cases of high treason, and petit treason, felony, and trespasses of all kinds, and in all pleas of the crown; though they cannot be used for injuries of a private nature, that neither concern the king nor the public; and therefore all *indictments* ought to be brought for offences committed against the common law, or against statutes; and not for every slight misdemeanor. A person cannot be indicted of suspicion of felony, but of the very crime itself; and then if he be not in custody, the sheriff is commanded to attach his body by a *capias*, &c. A person indicted for felony may have counsel allowed to speak for him, as to matter of law only; but such as are indicted for treason may have a copy of their *indictment* before trial, in order to advise

with counsel; and such *indictments* are to be found within three years after the offence committed, unless the treason be directly against the king's person. 7 & 8 W. III. cap. 3. which is extended to trials on impeachments by 20 Geo. II. cap. 30. Persons indicted of treason must be by the oaths of two witnesses; but in other cases one witness is sufficient. The prisoner, in this case, shall also have a copy of the *indictment*, but not the names of the witnesses, five days at least before the trial, i. e. upon the two confessions of the act. 7 W. III. cap. 3. before his arraignment; he shall also have a copy of the panel of jurors two days before his trial; and he shall have the same compulsion to bring in his witnesses for him, as was usual to compel their appearance against him. By 7 Ann. cap. 21. every person, indicted for high treason or misprision of treason, shall have not only a copy of the *indictment*, but a list of all the witnesses to be produced, and of the jurors impanelled, with their professions and places of abode, delivered to him ten days before the trial, and in the presence of two witnesses. But this list shall, so far as it affected *indictments* for the inferior species of high treason, respecting the coin and royal seals, is repealed by the statute 6 Geo. III. cap. 52. But no person indicted for felony is, or (as the law stands) can be, entitled to such copies, before the time of his trial.

Indictment must be certain in every point, and charge some particular offence; also goods stolen must be particularly set down, and the offence laid positively, and not by way of recital. These must also be expressed the Christian name, surname, and addition of the offender, with the day, year, and place in which the offence was committed, as also the nature of the offence. 1 Hen. V. cap. 5. In an *indictment* for murder, the length, depth, or other dimension of the wound, must be expressed, that a judgment may be formed whether it was mortal; and in this case, the time of the death must be laid within a year and a day after the mortal limb was given. See **APPRAISAL**. And in felony, the value of the things stolen is to be particularly mentioned, in order that it may appear, whether the offender has been guilty of grand or petit larceny. A mistake in spelling the defendant's surname is not a sufficient cause for abating the *indictment*, provided it sounds like it. If a word of consequence be omitted in an *indictment*, it renders the whole naught; but the case is not the same, where a word of form is omitted, or where there is an omission of a synonymous word, if the sense is not injured. In case one part of an *indictment* is inconsistent with another part of it, the *indictment* becomes void; though where the sense is plain, the court will dispose with a small inconsistency. *Indictments* are amendable the same term they are brought into court, but not afterwards; and in criminal prosecutions, the amendment must be only such as is permitted by the common law. *Indictments* for crimes committed, ought to be laid in the county where they were done; for otherwise, upon pleading the general issue, not guilty, if it appears that the offence was committed in another county or place different from that in the *indictment*, the defendant will be acquitted. An offender is subject to *indictment* for a felony committed against a person unknown; yet some body must be proved to be the proprietor upon the trial, or else the property will be presumed to be in the prisoner, he having pleaded not guilty. An *indictment* being at the king's suit, the prosecutor is a good witness to prove the charge contained in it; and no damage can be given to the party accused, except it be particularly grounded on some statute. *Indictments* before justices of the peace may be removed by certiorari into the king's bench.

A bill of *indictment* is said to be an accusation, because the jury, who inquire of the offence, do not receive it till the party that offered the bill, appearing, subscribes his name, and offers his oath for the truth of it. It is always at the suit of the king, and differs from an *accusation* in this, that the preference is no way tied to the proof thereof upon any penalty, if it be not proved, except there appear a conspiracy. But if any one prefer an *indictment* to the grand jury for any criminal offence, without probable cause, and the bill is not found, or the party is acquitted, action lies for a malicious prosecution. In order to which it is necessary that the plaintiff should obtain a copy of the record of his *indictment* and acquittal; but, in prosecutions for felony, it is usual to deny a copy of the *indictment*, where there is any least probable cause to found such prosecution upon. But an action for a malicious prosecution may be founded on such an *indictment* wherein no acquittal can be; as if it be rejected by the grand jury, or be *acquit non judice*, or be insufficiently drawn.

INDICTMENT, DEMURRER. See **DEMURRER**.
INDICTOR, in Law, he that indicteth another for an offence.

fence; and *indolent* is the party who is indolent. 1 Ed III. cap. 11. 21 Jac. I. cap. 6.

INDICUM. In the writings of the ancients we find this word very frequently used, as the name of a blue colour, or pigment, used in dying, and imported to Rome, Greece, and other parts of the world, from the East Indies. The greater number of writers make this the same with our indigo, or *indigo*; and some say it was the same with our woad; but the former opinion seems most probable.

This substance, which the Greeks call *indicon*, the Arabian writers, Avicenna, Serapion, and others, have called *ind*; though the same word is also sometimes used by them for the pigment made from woad.

INDICUM FAJIAN. See FELIUM and TAMARAFATRA.

INDICUS exilis. See COCCULUS.

INDICUS color, a term used by several of the ancient writers to express black. The generality of the Greek and Roman physicians of old times have called the black lignum aloes, *agallaban indicum*; and the only black kind of myrraban they were acquainted with, was in the same manner called the *indicum*; not that these were supposed peculiarly the product of the Indies, in distinction from the paler lignum aloes, or the other myrraban; but that they were of that colour which they called *indicus color*.

INDICUS effus. See CORRUPT.

INDIGENOUS, of *indigena*, denotes a native of a country; or that which was originally born or produced in the country where it is found. In this sense, particular species of animals and plants are said to be *indigenous* in the country where they are native, in opposition to *Exotic*.

INDIGESTION, a crudity, or want of due coction, either in a food, a humour of the body, or an excrement.

In the system of trituration, *indigestion*, which is a crudity, may be very naturally accounted for, from the relaxation of the fibres of the stomach. A bilious *indigestion*, in the opinion of Hequet, a great advocate for trituration, is owing to too much force in the stomach, or too much vivacity in its oscillations, which spoil the digestion, by rendering the trituration imperfect. But this is hardly satisfactory: for it should seem that digestion would be the more perfect, in proportion as the force of the stomach is increased. See DISSOLUTION, and TRITURATION.

INDIGITES, a name which the ancients gave to some of their gods.

There are various opinions about the origin and signification of this word; some pretending it was given to all the gods in general; and others, only to the semi-gods, or great men deified. Others say, it was given to such gods as were originally of the country, or rather such as were the gods of the country that bore this name; and others again hold, it was ascribed to such gods as were patrons and protectors of particular cities.

Lastly, others hold *indigites* to be derived from *indigiti*, or *in loco deorum*, or from *indus* and *ago*, for *ago*, *indigiti*, *indigiti*, which last opinion seems the most probable.

In effect it appears, 1. That these *indigites* were also called *local gods*, *dei loci*, or *topical gods*, which is the same thing. 2. The *indigites* were ordinarily men deified, who indeed were, in effect, local gods, being esteemed the protectors of those places where they were deified; in that the second and third opinion are very consistent. 3. Virgil joins *patrii* with *indigites*, as being the same thing. Georg. I. ver. 498. *Diu patrii, indigites*.

4. The gods to whom the Romans gave the name *indigites* were, Jannus, Vedio, Joveo, Remulus, all the gods of Italy; and at Athens, Minerva, Jove, Serapis; and at Carthage, Dido. It is true, we meet with Junius *indigiti*; but that Junius *indigiti* is Joveo, not the great Jupiter; as we may see in Livy, lib. i. cap. 3. in which last sense Servius alludes to; *indigiti* comes from the Latin *indigiti*, I am among the gods.

Among these *indigites* gods, there is none more celebrated, nor more extensively worshipped, than Hercules.

INDIGNATORIUS, a muscle thus called, as being supposed to draw the eye from its inner corner outwards, which gives an appearance of scorn and anger.

But this is properly a compound motion of two muscles; for which, see EYE.

This muscle is called by others the *relaxus externus*, and *obducens*; and by Albino, the *ABDUCTOR*. It is one of his *quatuor oculi oculi*.

INDIGO, Zail, or Indigifera, in Botany, a genus of the *diastylis distandria* class. Its characters are these: the flower is of the butterfly kind; the standard open, bordered, and reflexed; the wings are oblong, blunt, and spread open, as is also the keel, which turns backward; in the centre is situated a cylindrical germin, which becomes a taper pod, filled with kidney-shaped seeds. Miller enumerates five species, and Linnæus six.

The species commonly cultivated for use is the Guatimala *indigo*, with smooth arched pods, growing close to the branches, unequal winged leaves, whole lobes are blunt and oval. This is chiefly cultivated in the English plantations in America, and by the French; though the Jamaica wild *indigo*, and the Carolina *indigo*, have been used with advantage.

From this plant is extracted a dye's drug, of a deep blue colour, brought hither from the West Indies and America. It is also made in the East Indies, particularly in the dominions of the Great Mogul, the kingdom of Golconda, &c.

Labat has given a particular account of the culture of the plant, and the preparation of the *indigo*. The ground being thoroughly cleared from weeds (one of the principal points in the culture) a number of furrows, ranged in a line, march across, making little trenches of the width of their toes, and two or three inches deep, about a foot distant from one another every way; then, returning, they drop some seeds in each trench, and afterwards cover them with the earth taken out. In moist weather, the plant comes up in three or four days; and in about two months after, it is fit for cutting; if suffered to stand till it runs into flower, the leaves become too dry and hard, and the *indigo* obtained from them proves less in quantity, and less beautiful; the due point of maturity is known, by the leaves beginning to grow less supple, or more brittle. In rainy seasons, the cutting may be repeated every six weeks: cutting in dry weather kills the plant, which, if that is avoided, continues to afford fresh crops for two years.

A large quantity of the herb is put into a vat or cistern of strong mason work, with so much water as is sufficient to cover it; and some wood laid above, to prevent its rising up. The matter begins to ferment, sooner or later, according to the warmth of the weather, and the maturity of the plant, sometimes in six or eight hours, and sometimes not in less than twenty. The liquor grown hot, throws up a plentiful froth, thickens by degrees, and acquires a blue colour inclining to violet. At this time, without touching the herb, the liquor impregnated with its tincture is let out, by cocks in the bottom, into another vat placed for that purpose, so as to be commanded by the first.

In the second vat, the liquor is strongly and incessantly beat and agitated, with a kind of buckets fixed to poles, till the colouring matter is united into a body. A good deal of nicety is requisite in hitting this point: if the beating is ceased too soon, a part of the tinging matter remains dissolved in the liquor; if continued a little too long, a part of that which had separated is dissolved afresh. The exact time for discontinuing the process is determined, by taking up some of the liquor occasionally in a little cup, and observing whether the blue fecula is disposed to separate and subside.

The whole being now suffered to rest till the blue matter has settled, the clear water is let off, by cocks in the sides at different heights; and the blue part discharged by a cock in the bottom, into another vat. Here it is suffered to settle for some time longer, then further drained in cloth bags, and exposed in shallow wooden boxes to the air, without exposing it to the sun, and carefully keeping it from the rain, till thoroughly dry.

The author above mentioned, from whom the whole of the foregoing account is extracted, observes farther, that the goodness of the *indigo* depends greatly upon the age of the plant; that before it has grown fully ripe, the quantity it yields is less, but the colour proportionally more beautiful; that probably the secret of those whose *indigo* has been most esteemed, is no other than cutting the herb at the time when it yields the finest colour; that the superiority of some of the *indigo* of the East Indies to those of America, is perhaps owing to the former being prepared more curiously from only the leaves of the plant; and that by beating the herb in the sleeping-vat, which has been practised by some with a view to increase the quantity, great part of the substance of the leaves and bark is blended with the water along with the colouring matter, and the *indigo* extremely debased.

It is said that lime, or lime-water is sometimes employed in the beating-vat, to promote the separation of the tinging particles from the water; and that the hardness or firmness of some sorts of *indigo* is owing to an over proportion of this addition.

Pomet says, that the Indians of the village of Sarqueville, near Amadabat, use only the leaves of the *indigo*, and throw away the plant and branches; and from thence the most esteemed *indigo* is brought.

Indigo is commonly divided, from the colour which it exhibits upon breaking, into three kinds, copper-coloured, purple, and blue. It is said that the dyers use chiefly the first; and the callico-printers (for this drug gives a durable stain to linen as well as woollen) the last. On what particu-

particular circumstances these different appearances depend, we know not; nor is it certainly known, whether the real quality of the *indigo* has any connexion with them. The deepest and liveliest blue *indigo*, rubbed with the nail, appears like polished copper; and solutions of all the ferrous, made in alkaline fixivia, assume like a copper-coloured film upon the surface. Good *indigo* is moderately light, breaks of a shining surface, and burns almost wholly away upon a red-hot iron. It is quickly penetrated by water, and reduced into a kind of paste; a considerable part is at the same time diffused through the liquor, and very slowly sublimed. This is probably what Laves and Hellsor mean by its dissolving in water; for no part of the *indigo* really dissolves; it cannot indeed be expected that it should, from the process by which it is obtained.

Indigo requires an equal quantity or more of fixed alkaline salt, to render it totally soluble in water. On digesting the *indigo*, with a gentle heat, in the solution of the alkaline salt, a shining copper-coloured film begins to appear, and gradually covers the whole surface; on agitating the matter, a large blue flower or froth arises, and the liquor underneath appears of a deep green. If woollen cloth, without any other preparation than moistening it with warm water, be dipped in this hot liquor, it comes out perfectly green, and changes almost instantly in the air to a fine blue. This is the common process of dyeing blue.

Mr. Hellsor describes two *indigo* vats with urine; one of which is used like the foregoing, and the other cold. The hot vat consists of equal parts of *indigo*, alum, and tartar, dissolved in urine till the liquor becomes green. The cold one is prepared, by digesting powdered *indigo* with vinegar for twenty-four hours, in the proportion of four pounds to about three quarts; then mixing the matter with about fifty gallons of urine, and stirring the whole together every night and morning, till the liquor turns green, and gathers a head like the common vat.

Indigo is fitted for printing on linen, by diluting it with water into the consistence of a syrup; then adding some powdered pearl-shells, green vitriol, and lime newly slaked; with so much water, occasionally, as will reduce them into the consistence of thin paint; mixing the whole thoroughly together, and stirring the matter every now and then, till it gains a copper colour on the surface. The proportions used by the workmen are, two parts of *indigo*, one of pearl-shells, three of vitriol, and two of lime. The same composition, diluted with a sufficient quantity of water (about six gallons to a pound of *indigo*) and boiled, gives a durable blue to tanned skins, whether dipped in hot or cold.

Indigo digested in a moderate heat with different volatile alkaline spirits, gave only yellowish and brownish red tinctures; with rectified spirit of wine, a reddish one; to lime-water, and to water acidulated with the vitriolic, nitrous, and marine acids, it gave no tincture at all. The concentrated vitriolic acid unites with it into a smooth paste, especially if the *indigo* is previously well ground with powdered glass, sand, or other like substances. The *indigo* is thus rendered soluble in boiling water along with the acid, so as to pass through the pores of a filter; the solution, whilst hot, appears of a deep bright green colour, like that made by fixed alkalies, but fades as it grows cold, and changes at last to a brownish. These experiments, which were many times repeated with the same event, seem to overturn Mr. Hellsor's ingenious theory; which deduces the green colour of solutions of *indigo* from the common property of blue juices being turned green by alkalies; and the blue colour which the cloth acquires soon after it is taken out of the vat, from a separation of the alkali. We here find, that a green solution of this concrete is obtainable by the strongest of the acids, and that with volatile alkalies it discovers no tendency to greenness.

For the method of preparing *Saxon Blue* and *Saxon Green* from *indigo*, see those articles.

Indigo is sometimes used among the painters, for paper-hangings, and such gross uses, who grind and mix it with white to make a blue colour; for without that mixture it would paint blackish.

They also mix it with yellow, to make a green colour. It is also used in dyeing, and by the laundresses, to give a bluish cast to their linen.

In the *Hortus Indus Malabaricus* is an account of the plant whence *indigo* is drawn; the decoction of whose root is said to be excellent against nephritic colics; its leaves, applied to the abdomen, good to promote urine; and the *indigo* itself is said to be of good use in drying of tumors.

Some physicians have recommended *indigo* in the quantity of a dram, while others look upon it as a poison; and in Saxony the internal use of it is prohibited.

Indigo, *holland.* See AMORPHIA.

VOL. II. N° 184.

INDIRECT *modes of syllogism*, in *Logic*, are the five last modes, or *modi*, of the fifth figure, expressed by the barbarous words *baralipton*, *alantari*, *dabitis*, *jespame*, *frepton*.

It is the conversion of the conclusion which renders the *modes indirect*: for instance, *sylogismu in darii*, and *alantari* in *dabitis*, would be perfectly alike, were it not for that conversion; the propositions having the same quantity, and the same quality, and the middle term being the subject in the major, and the attribute in the minor, in both. It remains then, that, to make a distinction, that which is the subject of the conclusion in *darii*, be the attribute in the conclusion of *dabitis*; and that which is the attribute in the first, the subject in the last. See SYLLOGISM.

RI. There are afflictions which promote salvation:

TIS. Therefore some things promoting salvation are afflictions.

INDIRECT confirmation. See CONFIRMATION.

INDISCERNIBLES, in the *Philosophy of Leibnitz*. See LEIBNITZIAN philosophy.

INDIVIDUAL, INDIVIDUUM, in *Logic*, a particular being of any species; or that which cannot be divided into two or more beings, equal or unequal. The usual division in logic is made into genera or genera, those genera into species, and those species into individuals. See GENUS, SPECIES, and DIVISION. The schoolmen make a fourfold distinction of individuals; viz.

INDIVIDUUM *nagum*, that, which though it signifies but one thing, yet may be any of that kind; as when we say a man, a certain person, or one, said so and so; though but one person is meant, yet that person, for aught that appears to the contrary, may be any body.

INDIVIDUUM *designativum* is, when the thing is named and determined; as Alexander, the river Nile, &c. this is also called *individuum figuratum*.

INDIVIDUUM *demonstrativum* is, when some demonstrative pronoun is used in the expression; as, this man, that woman.

INDIVIDUUM *hypotheticum*, or by supposition, when an universal name or term is restrained, by the supposition, to a particular thing; as when we say, the son of such a one, and it be known that he had but one son.

INDIVISIBLES, in *Geometry*, those indefinitely small elements, or principles, into which any body or figure may be ultimately resolved.

A line is said to consist of points, a surface of parallel lines, and a solid of parallel and similar surfaces; and because each of these elements is supposed *indivisible*, if in any figure a line be drawn through the elements perpendicularly, the number of points in that line will be the same as the number of the elements.

Whence it appears, that a parallelogram, prism, or cylinder, is resolvable into elements, as *indivisibles*, all equal to each other, parallel, and like to the base; and a triangle into lines parallel to the base, but decreasing in arithmetical proportion; so also are the circles, which constitute the parabolic conoid, and those which constitute the plane of a circle, or the surface of an isosceles cone.

A cylinder may be resolved into cylindrical curve surfaces, having all the same heights, and continually decreasing inwards, as the circles of the base do, on which they infill. This way of considering magnitudes, is called the method of *indivisibles*, which is only the ancient method of exhaustion, a little disguised and contracted.

It is found of good use in shortening mathematical demonstrations; of which we may give an instance in that famous proposition of Archimedes, that a sphere is two thirds of a cylinder circumscribing it.

Suppose a cylinder, an hemisphere, and an inverted cone (Tab. III. *Geometry*, fig. 52) to have the same base and altitude, and to be cut by infinite planes all parallel to the base, of which *dg* is one; it is plain, the square of *ab* will every where be equal to the square of *ke* (the radius of the sphere) the square *bc* = *eb* square; and, consequently, since circles are to one another as the squares of the radii, all the circles of the hemisphere will be equal to all those of the cylinder, deducting thence all those of the cone; wherefore the cylinder, deducting the cone, is equal to the hemisphere; but it is known, that the cone is one third of the cylinder, and consequently the sphere must be two thirds of it.

Cavalleri was the first person who introduced this method of *indivisibles* into one of his works, entitled *Geometria Indivisibilium*, printed in 1635; which he also made use of in another tract published in 1647.

INDIVISO—*PER* INDIVISO. See **PRO**.

INDIVISUM FELUM. See **LEAF**.

INDOGFORUM PARLIAMENTUM. See **PARLIAMENTUM**.

INDORSEMENT, any thing written on the back of a

deed, or instrument. See **ENDORSEMENT**.

A condition written on the back of an obligation is com-

monly called an *indorsement*; from *in*, and *orsum*, back.

INDORSEMENT of a bill of exchange. See **ENDORSE-**

MENT.

INDUCEMENT, in *Law*, is what is alleged as a mo-

tive or incitement to a thing; and it is used specially in

several cases; viz. there is *inducement* to actions, to a

travel in pleading, a fact or offence committed, &c.

Inducements to actions need not have so much certainty

as in other cases: a general *inducement* is not sufficient,

where it is the ground of the action; but where it is

only the *inducement* to the action, as in consideration of

forbearing a debt until such a day (for that the parties

are agreed upon the debt) this being but a collateral pro-

mise is good without showing how due.

INDUCIARUM PETITIO. See **PETITIO**, and **EMPARANCE**.

INDUCTION, in *Logic* and *Rhetoric*, a consequence

drawn from several propositions, or principles, first laid

down.

Thus, the conclusion of a syllogism is an *induction* made

from the premises. See **SYLLOGISM**.

INDUCTION is also used for a kind of syllogism itself; be-

ing a medium between an **ENTYME** and a **GRAD-**

ATION, in regard it wants a proposition (which, how-

ever, is understood), as in the *entymeme*; and abounds

in assumptions (which yet are collateral, or of the same

degree), which is the case in a *gradation*.

For instance; every terrestrial animal lives, every aerial

animal lives, every aquatic animal lives, and every rep-

tile animal also lives; therefore every animal lives.

Here, it may be observed, are various assumptions, from

the more general species of the animal kind collected into

one; which this proposition is supposed to precede; e. g.

that every animal is either terrestrial, aerial, aquatic, or

reptile.

Suidas reckons three kinds of *induction*: that just men-

tioned, which concludes or infers some general propo-

sition from an enumeration of all the particulars of a kind

he calls the *diastole induction*.

The second proceeds by interrogation, and concludes

probably, or with a verisimilitude; this is what the

Greeks called *anagoge*, and was that which Socrates

calmly made use of, as Cicero, in his *Topics*, and

Quintilian have observed; and, therefore, called the *syn-*

cretic induction. This, however, is a cautious way of

reasoning; for while the respondent is not aware of what

is designed to be inferred, he is easily induced to make

those concessions, which otherwise he would not. Be-

sides, it is not so well suited to continued as to inter-

rogatory discourses.

The third kind of *induction* is properly rhetorical; being

a conclusion drawn from some example, or authority.

This is a very imperfect *induction*, all its force lying in a

proposition which is concealed, and which will hardly

bear being exprest. Thus, he that says, Codrus died

bravely for his country, therefore I must die bravely for

my country; proves nothing, unless this proposition be

carried in mind, that I must do the same with Codrus.

Again, Archimedes, and the other mathematicians, say,

the sun is much bigger than the earth; therefore, it must

be owned, the sun is much bigger than the earth. Where

this proposition is understood, viz. whatever Archimedes,

and the other mathematicians, say, is true.

Induction is one of the four forms of reasoning used by

orators in *confirmation*; the other three are **SYL-**

LOGISM, **ENTYME**, and **EXAMPLE**, which last

coincides with the third species of *induction* above enu-

merated.

INDUCTION, in the *English Laws*, is usually taken for the

giving possession to an incumbent of his church, by lead-

ing him into it, and delivering him the keys, by the com-

missary, or bishop's deputy, and by his ringing one of

the bells.

When a clerk is instituted into a benefice, he is to ex-

hibit his mandate from the bishop to the archdeacon, or

other person to whom it is directed, and hath a right

thereby to be *inducted* into his living; and if he be re-

fused *induction*, he hath a remedy both in the ecclesiastical

court, and also an action of the case in common law,

against the archdeacon. If the *inductor*, or person to be

inducted, be kept out of the church, or house, by lay-

men, the writ *de vi laica* lies for the clerk, which is di-

rected out of the chancery to the sheriff of the county,

to remove the force, &c. If another clergyman, presented

by the same patron, keep possession, a spoliation is grant-

able out of the spiritual court, whereby the tithes, &c.

shall be sequestrated, till the right be determined.

The archdeacon rarely *inducts* a clerk in person, but usu-

ally issues out a warrant to the clerks and lettered persons

within the archdeaconry, empowering any of them to do

it in his stead.

An *induction* made by the patron of the church is void;

but bishops and archdeacons may *induct* a clerk to the

benefices of which they are patrons, by prebication.

No *induction* is necessary to a *donative*, where the pa-

tron, by donation in writing, puts the clerk in possession

without presentation. 1 Hen. IV. cap. 7.

The usual form and manner of *induction* is, for the *in-*

ductor to take the clerk by the hand, and then to lay it

on the key of the church, which must be then in the

door, and to say, "By virtue of this instrument, I *induct*

"you into the real, actual, and corporal possession of

"the rectory or vicarage of—, with all its fruits, pro-

"fits, members, and appurtenances."—This done, he

opens the door, and puts the clerk in possession of the

church, and shuts the door upon him; who, after he

hath a tolled a bell (if there be any) to give the parishioners

due notice and sufficient certainty of their new minister,

comes out, and delivers the *inductor* to indorse a certifi-

cate of his *induction* on the archdeacon's warrant, and

that all present will signify it under their hands. If the

church-key cannot be had, it is sufficient that the clerk

lays hold of the ring of the door, the latch of the church

gate, &c. and, within two months after this, the clerk

must read the thirty-nine articles, and all the service of

the day, both at morning and evening-prayer, in the

parish church of his benefice, and in the time of common

prayer, and declare his assent and consent; he must

also then read the ordinary's certificate, in which is the

declaration of his conformity, together with the same

declaration, and of all this he must have two or three good

witnesses, who must sign that they heard him do it, and

be ready to attest it, *in case*, if required; and, within

six months after *induction*, he must also take the oath of

allegiance, supremacy, and assent; at the quarter-

sessions, or in some one of the courts at Westminster-

hall.

Induction makes the parson complete incumbent, and

fixes the freehold in him. When a clerk is thus preben-

ded, instituted, and *inducted* into a rectory, he is then,

and not before, called in *law per son imperpetuum*, or par-

son *imperpetuum*. 13 Eliz. c. 12, 13 and 14 C. II. c.

II. c. 23.

INDULGENCE, in the *Romish Theology*, the remission

of a punishment due to a sin, granted by the church, and

supposed to save the sinner from purgatory.

The Romanists found their *indulgences* on the infinite

treasure of the merits of Jesus Christ, the Holy Virgin,

and all the saints; which they suppose the church has a

right of distributing, by virtue of the communion of

saints. See **SUPEREROGATION**.

These *indulgences* were first invented in the eleventh century

by popes Gregory VII. Victor, and Urban II. as a recom-

pense for those who went in person upon the wild

enterprise of conquering the Holy Land. See **CRUSADES**.

They were afterwards granted to those who hired a sol-

dier for that purpose, and in process of time were be-

stowed on such as gave money for accomplishing any

pious work enjoined by the pope. In the beginning of

the twelfth century, the bishops, whenever they wanted

a supply of money for their private pleasures, or the

exigencies of the church, resorted to the scandalous traffic

of *indulgences*; and when the Roman pontiffs saw that

immense treasures were thus accumulated by the inferior

rulers of the church, they thought proper to limit the

power of the bishops in remitting the penalties imposed

upon transgressions, and assumed it, almost entirely, as

a profitable traffic to themselves. They began with grant-

ing a plenary remission of all the temporal pains and pe-

nalities which the church had annexed to certain tran-

sgressions; and then proceeded to abolish even the penit-

ences which are referred in a future state for the workers

of iniquity.

The Roman **JURIS**, first instituted by Boniface VIII.

A. D. 1300, grants with it a plenary, or full *indulgence*,

for all the crimes committed therein.

The pope also grants bulls of plenary *indulgence* to several

churches, monasteries, and even to private persons;

and it is a frequent thing to have general *indulgences* for

the time of the principal feasts of a year. Their casuists

say, that a plenary *indulgence* does not always prove ef-

fectual, for want of complying with the conditions

whereon it was granted.

For the extirpation of heretics it has been a common

practice with the popes to grant *indulgences*. Thus Cle-

ment XII. "That we may stir up and encourage the

"faithful to exterminate this unchristian crew of for-

"lorn wretches, [the Covenanters, when in arms against

"Lewis

"Lewis XIV.] we fully grant and indulge the full remission of all sins, whatever they may be (relying upon that power of binding and loosing, which our Lord conferred upon his chief apostle, to all those that shall lift themselves in this sacred militia, if they shall happen to fall in battle." See ANNOTATION.

Julius II. had bestowed *indulgences* on all who contributed towards building the church of St. Peter at Rome, and pope Leo X. in order to carry on this magnificent structure, published *indulgences*, and a plenary remission on the same pretence. Enrolling these *indulgences* in Germany, together with a share in the profit arising from the sale of them, to Albert, elector of Mentz, and archbishop of Magdeburg, who employed Tetzel, a Dominican friar, as his chief agent for retailing them; and he farmed out those of other countries to the highest bidders, who, to make the best of their bargains, procured the ablest of their preachers to extol the value of the same: "Happy times for sinners, says a modern writer, their crimes were rated, and the remission of them set up by auction. The apostolic chamber rated fine at a pretty reasonable rate; it cost but nine shillings and a few pence, for crimes which people on this side the Alps punished with death."

These are specified in a book of rates, called the Tax-Book of the Holy Apostolic Chancery, first printed at Rome in the year 1514, and ascribed by some to pope Innocent VIII. From a correct edition of this book, printed by L. Danck, professor at Norwiche, in Gothland, in 1651, it appears that the price of absolution for fornication, attended with the most heinous circumstances, was six groats or groats; for a layman murdering a layman, five groats; for laying violent hands on a priest, without shedding blood, nine groats; for committing incest, five groats; for a priest's keeping a concubine, seven groats; for forging the pope's hand-writing, sixteen or eighteen groats. See the Taxa S. Cancellarie Apostolicæ, a L. Danck, Francofurti, 1651, p. 126, &c. It was this great abuse of *indulgences*, that contributed not a little to the first reformation of religion in Germany; wherein Martin Luther began first to declaim against the preachers of *indulgences*, and afterwards against *indulgences* themselves: but since that time, the popes have been more sparing in the exercise of this power; however, they still carry on a great trade with them in the Indies, where they are purchased at two reals apiece, and sometimes more. See REFORMATION.

INDULGENCE, or **INDULT**, signifies also a special favour, or privilege, conferred either on a community, or a particular person, by the pope's bulls; in virtue whereof the party is licensed to do or to obtain something contrary to the intention and disposition of the common laws.

There are two kinds of *indults*: the one *active*, which consists in a power of nominating and presenting freely, and without reserve, to benefices that are otherwise limited, and restrained by the laws of the apostolic chancery; such are those ordinarily granted to secular princes, cardinals, bishops, &c.

Passive indults consist in a power of receiving benefices, and expectative graces of which kind are those of a parliament, of graduates, and mandatories.

The *indult* of kings is the power given them of presenting to consistorial benefices, either by treaty, by favour, or special privilege.

The *indult* of cardinals is a licence for holding regular as well as secular benefices, and for disposing of benefices in commendam, or continuing them, &c.

Indults of parliament is a right of privilege granted to the chancellor, presidents, counsellors, and other officers in the parliaments of France, to obtain a benefice of the collator, upon the king's nomination directed to him. This is a kind of advowson, or patronage, belonging to the French king; the *indults* being a mandate, or grace, by which he is permitted to name to any collator he pleases, a counsellor, or other officer of parliament, on whom the collator shall be obliged to bestow a benefice; so that the right of the *indults* reverts radically in the king, the officers being only the objects thereof.

INDULTO, in Commerce, denotes a duty, tax, or custom paid to the king of Spain for all such commodities as are imported from the West Indies in the Galleons.

INDURATING, a term applied to such things as give a harder or firmer consistence to others, either by the greater solidity of their particles, or by dissipating the thinner parts of any matter, so as to leave the remainder harder.

Thus a tumor is *indurated*, either by the addition of earthy and solid particles, as in the scirrhus, and knotty swellings; or by transpiring the thinner parts through the skin, whereby the remainder grows more fixed, as in an osteoma.

INDUSIUM, in the *Healing Art*, a shirt or shift. It has been a controverted point, among some physicians, whether it is proper to change the linen in some distempers or not? the whole of which may be reduced to this: if a person does not sweat; there seems to be but very little danger of taking cold; and then clean and fresh linen is not only agreeable but of use, as it contributes to promote perspiration. If the patient sweats, provided these sweats are symptomatic, it does no injury to check them; if critical, it may not be so prudent to change the linen while they flow plentifully; but if they cease, there is more danger of taking cold from the wet linen, than there is from changing it, provided it is previously well aired. In all cases, the perspirable matter, or that of sweat, impregates the linen, and becomes in some degree acrimonious; which must have a very bad influence, in acute distempers particularly. And that the acrimony contained in linen, may have a very bad effect in the body, Dimerbrook confirms by a memorable instance of some person or persons, who, upon recovery from the plague, relapsed immediately and died, upon putting on linen washed with soap.

As many persons contract a habit of wearing flannel shirts or shifts; in order to set them right, we shall give the judgment of Wainwright thereon.

The most certain and constant effect of wearing flannel, is to make a more free and plentiful perspiration; which, though it be attended with great advantages (according to Sanctorius) with moderate; yet when excessive, nothing is more pernicious. But since the increasing one evaluation is the lessening of another, therefore, whenever too much is thrown off from the blood, either by stool, urine, or saliva; then indeed it may be proper to wear flannel.

That it may appear how prejudicial flannel is to those who perspire too much, as most weak people do, and to those the wearing of flannel is generally prohibited, it may be observed from Sanctorius, that insensible perspiration is double to the sensible evacuations, made by urine and stool put together; and that it is to that made by stool, as forty to four; so that it is ten times more than that by stool. Therefore a man will be made no weaker by having ten times as many stools as he used to have, than he will by perspiring only double the quantity he usually does. Farther, if we consider, that the greatest part of our stools is the remains of our food that could not enter the lacteals, we shall find the difference much greater: for it cannot be imagined, that above one tenth of what we void by stool is evacuated from the mass of blood by the liver and intestinal glands; so that upon this account there is as much derived from the mass of blood in one day by perspiration, as by stool in an hundred. Therefore, if perspiration by any means be doubled, in twenty-four hours it will make a man as faint, as if he had an hundred times more stools than usual: and there are none but who expect a weakness from an unusual purging; and we daily experience the sudden danger of a diabetes wherein the quantity of urine is increased; but take little notice of an increased perspiration, because insensible: for which reason we ascribe the mischief it occasions to some other cause.

If what has been said is of force sufficient to persuade any to leave off wearing flannel; it should be forbore in a warmer season; and at the same time use should be made of a cold bath or a flesh-brush, which will prevent the inconveniences that might otherwise attend it.

INDUSTRY, *fruits of*. See **FEWIT**.

INEQUALITY of natural days. See **EQUATION**.

INEQUALITY, optical. See **OPTICAL**.

INERTIÆ vis. See **VIS INERTIA**.

INESCUTCHEON, in Heraldry, a small escutcheon borne in a larger one, as part of some other coat. Tab. II. Heraldry, fig. 63. See **ESCUTCHEON**.

Guillem confines the name to an *escutcheon* borne single in the fess point or centre.

This is also sometimes called an *escutcheon of pretence*. He who marries an heiress, bears her coat of arms on an *inescutcheon*, or *escutcheon of pretence*, in the middle of his own coat.

Modern heralds apply the name *inescutcheon* to those small escutcheons, several of which are borne in a large one.

IN ESSE is applied to things which, are actually existing.

Authors make a difference between a thing *in esse*, and a thing *in posse*. A thing that is not, but may be, they say, is *in posse*, or *potentia*; but a thing apparent and visible, they say, is *in esse*, that is, it has a real being *co-existent*; whereas the other is casual, and at best but a possibility.

INFALISTATIO, an ancient punishment of felons, by throwing them among the rocks and sands, customarily used in port-towns. It is the opinion of some writers, that *infelstatus* did imply some capital punishments, by expelling

exposing the malefactor upon the sands till the next tide carried him away; of which custom, it is said, there is an old tradition. However the penalty seems to take its name from the Norman *falsus*, or *faulus*, which signified not the sands, but the rocks and cliffs adjoining, or impeding on the sea-shore. *Commisio solutio ad quam fuit falsipens, allegatus, vel alio modo morti damnatus, &c. vel apud Ducez infallitatus, apud Southampton falsipens, &c.*

INFALLIBLE, from *in*, taken privatively, and *falsus*, I deceive, that which cannot deceive, or be deceived.

Upon this term stands one of the principal heads of controversy between the Reformed and the Catholics: the latter of whom maintain, that the church, assembled in general council, is *infallible*: which the former deny.

The **JESUITS**, in their disputes with the **JANSENISTS**, have expressly asserted that Jesus Christ hath given to all popes, whenever they shall speak *ex cathedra*, the same *infallibility* which he had, both in matters of right and fact.

The principal reasons alleged for the *infallibility*, are drawn from the promises of Christ, from the obscurity of the Scriptures, the insufficiency of private judgment, and the necessity there is of some *infallible* judge for the decision of controversies.

The *infallibility* of the pope is a doctrine of a late standing, and is not entirely acquiesced in, even in their own communion, and altogether rejected by the Gallican church.

INFAMOUS, derived from *in*, and *fama*, fame, report, in the ordinary use of the word, signifies something notoriously contrary to virtue, or honour.

Aulus Gellius uses the word *infamatus*, *infamatus*, for what we ordinarily call *paradoxical*, i. e. discourses remote from the common opinion's propositions that appear opposite to truth, &c. as the clergy of Therites, the praise of a quarant age, &c.

INFAMOUS, in *Law*, denotes a person, or thing, which is of no repute, or esteem, in the world.

There are two kinds of *infamy*. Some persons being *infamous* as having been noted by the laws, or stigmatised by public judgment.

Infamy, which extends to forgery, perjury, gross cheats, &c. disables a man to be a witness or juror; but a pardon of crimes restores a person's credit to make him a good evidence. Judgment of the pillory makes *infamy* by the common law, but by the civil and canon law, if the cause for which the person was convicted was not *infamous*, it infers no *infamy*.

Others are held *infamous*, by the exercise of some scandalous profession; as a cataphile, a merry andrew, a hangman, an informer, &c.

Hencefore there were crowns of *infamy* given, by way of punishment, to criminals: they were made of wool.

INFANCY, from *in*, and *fans*.

INFANT, in a *Law* sense, a person under the age of one-and-twenty years, whose acts are in many cases either void or voidable. All gifts, grants, &c. of an *infant*, which do not take effect by delivery of his hand, are void; and if made to take effect by delivery of his own hand, are voidable by himself and his heirs; and those who shall have his estate. An *infant* may bind himself to pay for necessities, as meat, drink, apparel, and learning, but not by bond with penalty; though a bill for necessities, without a penalty for the very sum due, it is said, will bind him. *Infants* are not obliged to pay for cloaths, unless it be asserted for their own wearing; and that they were convenient and necessary for them to wear, according to their degree and estate. An *infant* may buy, but cannot borrow money to buy necessities; for the law will not trust him with necessities, but at the peril of the lender, who must lay it out for him in necessities, or for it thus laid out.

An *infant* has been adjudged of age the day before his birth-day; for the law will not make a fraction of a day; therefore where a person was born the third of September, and the second of September twenty-one years after, he made his will, it was held good, and that he was then of age to devise his lands. And it is said such will shall take effect, though the testator dies by six at night of that day.

An *infant* eight years of age, or upwards, may commit homicide, and be hanged for it, if it appear, by any other acts, that he had knowledge of good and evil; for here *malitia supbiait animus*. See COKE on Littleton, sect. 465, says, "An *infant* shall not be punished till the age of fourteen"; which, according to him, is the age of discretion.

But this depends on the degree of judgment which he possesses. If an *infant* be *infra annos infantie*, viz. seven years old, he cannot be guilty of felony, whatever circumstances proving discretion may appear. See AGE, in *Law*, EXECUTOR, GUARDIAN, &c.

By the custom of *Gavet-kind*, an *infant*, at the age of fifteen, is reckoned at full age to sell his lands; and by custom in some places, an *infant* seized of land in *advowson*, may, at the same age, make a lease of years, that shall bind him after he comes of age. By the custom of London, an *infant*, unmarried, and above the age of fourteen, may bind himself apprentice to a freeman of London, by indenture, with proper covenants, which shall be binding.

An *infant* in *utero fa mris*, or in the mother's womb, is capable of having a legacy, or a surrender of a copyhold estate made to it. It may have a guardian assigned to it; and is enabled to have an estate limited to its use, and to take afterwards by such limitation, as if it were then actually born; and in this point the civil law agrees with ours. Though *infants* cannot alien their estates, yet *infant* trustees or mortgagees are enabled to convey, under the direction of the court of chancery or exchequer, or other courts of equity, the estates they hold in trust or mortgage, to such person as the court shall appoint.

An *infant*, who has an *advowson*, may present to the benefice when it becomes void. An *infant* is capable of inheriting, and may also purchase lands, but his purchase is incomplete; for, when he comes to age, he may either agree or disagree to it, without alleging any reason; and so may his heirs after him, if he dies without having completed his agreement. And in case any *infant* bargain and sell his land by deed, indented and enrolled, yet he may plead non-age.

If an *infant* grants leases for a term of years, he may, at his full age, either confirm the lease, or bring treple against the lessee for the occupation. Also a lease granted to an *infant* may be avoided by waiving the land before the rent-day expressed therein. However, *infants* are bound in all acts of necessity; as presentations to benefices, admittances and grants of copyhold estates, assenting to legacies, and conditions annexed to lands, whether the estate comes by grant or descent. If an *infant* be the defendant in an action, the plaintiff shall have six years for commencing his action, after the defendant comes of age; and an *infant*, who is a plaintiff, has also six years after he comes of age, to sue by the statute of limitations.

INFANT, Disimpratures of INFANTS. It is to be observed in general, that all *infants* are not equally exposed to disimpratures of many kinds, but that the children of persons of tender constitutions and idle lives are most subject to them. The children of poorer people, which are usually hardly brought up from the first, are also less troubled with disorders, in general, than those which are taken more care of; and all their lives afterwards are much slier to bear external injuries, and are much less affected by them.

The several disimpratures of *infants* are these: *immobility at the birth*, called by authors *anasthesia*. In this case, the *infant*, as soon as born, remains immovable in its position, as if dead. It is to be brought to life and motion in this case, by breathing into its mouth, and burning saltpetre under its nostrils, letting it receive the same of it, and sprinkling cold water or wine upon it. When the case is less violent, the *infant* is often brought to itself, by applying it immediately to the breast and letting it suck; and in the other cases, this is very proper, after the before mentioned means have been used.

A yellow colour of the skin is another very common complaint in new-born *infants*, so that they look as if they had the JAUNDICE. This is an accident of no ill consequence. It often goes off of itself, after voiding the first stools; and if it does not, is easily removed by giving the *infant* a small quantity of syrup of rhabarb, and of the common absorbent powders, with antimonial diaphoreticum. In this case the child is to be kept warm, so that it may sweat moderately while it takes these medicines.

Difficulty of swallowing is also a common complaint in *infants*. If this happens from that fault of the frenulum of the tongue, which renders the child *tynguæ-tied*, as the good women express it, this is to be removed by cutting it. If it be caused by aphthæ, or little ulcers in the mouth, these are to be treated as below. If it proceed from a tumor of the tongue, the disquiet waters are to be put in small quantities into the mouth every two or three hours; and if there be ulcerations upon the tongue, the best of all applications is the oil of eggs. But before any thing is done for the child, it is necessary to see whether the fault be not in the mother from her having no milk, or from the nipples being so deprelled that the child cannot use them.

Impurities of the necessary parts. These sometimes happen in *infants*, so that there is either no passage for the stools, or for the urine: sometimes for neither. This case is rare; but when it happens, speedy help must be had, or the *infant* perishes. In cases where the passage

is regularly formed, but is only stopp'd up by mucous matter, which sometimes happens; the gentle abstergers are to be given, as the crabs-eyes or some other absorbent, half sized with an acid; and cocotte must be had to the use of a small catheter or glyster-pipe. But when there is a preternatural membrane formed, which stops the passages, this must be cut through by a surgeon.

The nostrils of infants are often plugged up with a gross mucus, which prevents their breathing freely, and likewise renders it difficult for them to suck or swallow. In oblique cases, after a suitable purge, two or three grains of white vitriol, to which some add the same quantity of vitriolam, dissolved in half an ounce of marjoram water, and filtered, may be applied now and then to the nostrils with a linen rag. But in common it will be sufficient to rub the nose at bed-time with a little sweet oil, or fresh butter.

Retention of the first stool; or MECONIUM, which is in the bowels at the time of the birth. This distemper in the body occasions the infant many severe pains, and throws it into great dangers; difficulty of breathing, pains in the abdomen, inquietude, and convulsions, are the consequences of it. Nature often cures these by a discharge of bilious acid stools, which are sometimes green, sometimes yellow like the yolk of an egg. When nature is not able to do this in time, she is to be assisted by a little manna or magnesia alba; or a common spoonful of whey, sweetened with a little honey, will answer the purpose. The most proper medicine for expelling the meconium is the mother's milk, which is always, at first, of a purgative quality. Were children allowed to suck as soon as they show an inclination for the breast, they would seldom have occasion for medicines to discharge the meconium; but even where this is not allowed, they ought never to have daubs of syrup, oils, and other indigestible stuff crammed down their throats.

Stagnation of the breast attend some infants in such a degree, that they seem asthmatic. In these cases the solutive syrups of rhubarb and roses are to be given; and afterwards the pectorals, as the syrup of erythraem and maldenair, or syrup of liquorice. An emetic may also be given of the syrup of conserve of peach-blissoms, and a single grain of calomel, or two or three small, may be given and often have great success. If the fall, small doses may be given of powders prepared of diaphoretic antimony with twice its weight of deomated nitre, and the common resolvents, such as the orris root and spermaceti, may be added; and sometimes it is necessary to add a small dose of tartarum vitriolatum, with some of the common absorbent powders. See CAUPE.

Cough sometimes attend infants, but they are seldom oblique, usually giving way to the common pectoral syrups, or a little spermaceti, after the bowels have been unloaded by the laxative syrups, or other gentle cathartics. See CUTELOUGH.

Corpsas and gravitas happen also sometimes to infants; in these cases the common syrups before prescribed are to be given; and if they fail of effect, the nurse must take the medicines proper in these cases; which see under their proper heads.

Ruining of the eyes and ears. This is a very common complaint, and is to be cured by small doses of decoctions of pimpernel-root, fassiras, and the other sweetening woods, and by gentle laxatives on the intermediate days, in which calomel in small doses of a grain or two ought always to have its part; and the more acrid the matter discharged is, the more necessary is it to add to these things the mucilaginous medicines, such as the solutions of gum arabic and tragacanth in water, and mucilage of the seeds of quinces made by gently boiling them.

Chafings of the flesh are very common in infants, and usually arise from the sweats, urine, or acrid stools discharged upon the parts, especially when their nurses are so careless as to keep them dirty, and suffer those things to remain long on the parts. In this case common flour or powder, will often prove a cure; or, when that fails, a little camphor and ceruvis mixed among it, usually prove effectual. One of the best applications for this purpose is a solution of fuller's earth in a sufficient quantity of hot water, which should be gently rubbed, when cold, upon the galled parts once or twice a day. See EXCORIATION and GALLING.

But if internal causes concur, such as sharpness of the blood, and humours in the child, then the common absorbent and sweetening powders are to be given internally, at the same time that the others are applied externally to the parts.

The most effectual means for preventing these chafings are to wash the parts frequently with cold water, to change the linen often, and to keep the child in all respects thoroughly clean.

Foulings, in infants, are rather salutary than hurtful, provided they are moderate; but when they are violent, they are to be removed by giving gentle glysters, to give a derivation to the mucous matter downward, and at the same time applying externally the common strengthening and romachic plasters, as oil of mace, and the like, and repeating these applications as often as found necessary.

When vomiting is occasioned by too much food, it ought to be promoted by a few grains of ipecacuanha, or by making the child drink freely of lukewarm water, or weak infusion of camomile flowers. When the food has been of an acrid or irritating quality, a milder aliment should be substituted in its stead. When vomiting proceeds from an increased degree of sensibility, or too great an irritability of the nerves of the stomach, such medicines as have a tendency to brace that organ and abate its sensibility, must be used. The first intention may be answered by a slight infusion of the Peruvian bark, with the addition of a little rhubarb and orange-peel; and the second by the saline draughts, to which a few drops of liquid laudanum may be occasionally added.

Diarrhoea in infants are usually attended with pain, and the stools are four, slimy, green, or curdled: it is not safe to use astringents to them, but they may generally be cured by a gentle vomit of ipecacuanha, and afterwards small and gentle doses of rhubarb, interposing absorbent medicines to mitigate the acrimony of the humours. The best purge in this case is magnesia alba, which is absorbent and laxative, and operates without exciting gripes. The antimonial wine, acting both as an emetic and purge, is an excellent medicine in this case; and it may be diluted with water to suit the weakest constitution. If any gripings should remain, after the stomach and bowels have been cleansed, a tea-spoonful of syrup of poppies may be given in a little simple cinnamon water, three or four times a day, till these symptoms have ceased. See DIARRHOEA.

Costiveness in infants is a much more dangerous complaint, subjecting them to many disorders. The common purgative syrups of roses and peach-flowers are to be given in this case, as also emollient clysters; and suppositories are to be applied, for which purpose nothing is so proper as a piece of parley-root cut into a proper shape, and introduced after rubbing it over with butter. Haister recommended two or three grains of rhubarb in solutive syrup of roses, or a solution of manna, till the child's belly is opened, and afterwards the tefaceous powders. It is necessary, however, to distinguish this costiveness from a natural firmness of the stools when they are voided at moderate distances of time, and without pain; for this is a very salutary habit in children, after the meconium is voided in the first stools: it shews a strength in the child, and is to be accounted a good symptom. See COSTIVENESS.

Addition accompany most diseases of children, and are oftener the effect than the cause of those diseases. When green stools, gripes, purgings, four smalls, &c. shew, that the bowels abound with an acid, the child should have a little small broth, with light white bread in it, and sufficient exercise to promote the digestion. The tefaceous powders which have been customarily administered in this case, should never be given unless mixed with purgative medicines, as rhubarb, manna, or such like. The best medicine is the magnesia alba, which purges, and, at the same time, corrects the acidity. It may be given in any kind of food, or in the *lactarior absorbent mixture*. When an infant is troubled with gripes, its body should be opened with an emollient clyster, or the medicine just mentioned; and at the same time a little brandy may be rubbed on its belly with a warm hand before the fire: but brandy, spices, and other hot things should be avoided; except in cases where the above method fails; in which a little brandy or other spirits may be mixed with twice the quantity of warm water, and a tea-spoonful of it given frequently till the infant be easier. Sometimes a little pepper-mint water will answer the purpose very well.

Cutaneous eruptions. These attend children in various forms, and are of very different kinds; they are chiefly owing to improper food and neglect of cleanliness: a proper attention to these will generally be sufficient to remove them; but if this fails, some drying medicines will be necessary. Whilst they are applied, the body should be kept open, and cold carefully avoided. For this purpose, a little of the flowers of sulphur may be mixed with fresh butter, oil, or hog's lard, and the parts affected frequently touched with it. See ACNOR, CRUSTA LACTES, TINEA, and CUTELRANES.

Aphtha. In this complaint infants are found to have their tongues covered over with little whitish ulcers, affecting also the whole inside of the mouth, throat, and

stomach: and sometimes reaching through the whole intestinal canal, in which case they are very dangerous. See *APHTHA*.

This disorder sometimes arises from internal heat, sometimes from the frequency and eagerness of the child's suckling. The mouth in this case is to be wiped and cleaned frequently with a rag dipped in wine and honey, or with a cotton cloth dipped in syrup of marsh-mallows; or, with the following mixture, made of fine honey an ounce, borax a dram, burnt alum half a dram, and rose-water two drams. A very proper application in this case is a solution of ten or twelve grains of white vitriol in eight ounces of barley water. The most proper medicines for the spithead or thrush, are vomits of ipecacuanha, emetic tartar, or antimonial wine, and gentle laxatives. Five grains of rhubarb, and half a dram of magnesia alba may be rubbed together, and divided into six doses, one of which may be given every four or five hours, till they operate. Calomel has been sometimes used; but it often occasions gripes and sometimes convulsions. and, therefore, should be given to infants with the greatest caution.

Convulsions. These are caused in children by several different means, and therefore require a different treatment. Whatever greatly irritates or stimulates the nerves may occasion convulsions. Hence infants whose nerves are easily affected, are often thrown into convulsions by any thing that irritates the alimentary canal; by teething; strait clothes; and the approach of the small pox, measles, or other eruptive diseases. If they arise from a repulsion of sweats, the common alexipharmics are to be given, and in the intermitting times small doses of mercurius dulcis. If they are owing to acrimonious humours in the bowels, the cure may be begun with a clyster, and afterwards a gentle vomit, which may be repeated occasionally; and the body in the mean time kept open by gentle doses of magnesia alba, or small quantities of rhubarb mixed with the powder of crab's claws. When they are caused by abundant ferocities, valerian root and aurum soliminis are greatly recommended. When they are epileptic, and return very frequently, cinabar is to be given freely in powder; and when they are owing to worms, mercurius dulcis is the best of all remedies.

Convulsions which precede the eruption of the small-pox or measles generally go off when these make their appearance. And, therefore, a little time, bathing the feet, and throwing in a mild clyster will for all to rights. When convulsion has attended digestion, besides gentle evacuations, blistering may be proper, and the use of antispasmodic medicines, as the tincture of foot, asa fetida, or caltra. When convulsions proceed from any external cause, as strait clothes and bandages, these ought to be immediately removed. Convulsions that are not owing to any of the complaints already recited, most probably proceed immediately from the brain: but these seldom happen. In endeavouring to remove these, the chief intention is to make some derivation from the head, by blistering, purging, &c. If these fail, issues or setons may be put in the neck or between the shoulders.

For other diseases of infants, see *DENTITION*, *HYDROCEPHALUS*, *RICKETS*, and *WORMS*.

It is to be observed in general, that of the diseases of children the far greater number are wholly owing to external causes, very few of them to any internal fault in the constitution. The principal of these external causes, are the following:

1. Changes of the temperature of the air. These are brought on in regard to infants at the nurse's pleasure, and it is often thrown into too profuse sweats by a close room and too warm covering, and perhaps in the midst of this sweat is immediately taken from under that covering, and exposed to the open air. To this is owing most of the catarrhal affections to which infants are subject, and their fevers and cutaneous eruptions of the first kind.

2. Improper food and drink are another great source of the diseases of infants. Nurses frequently starve children, and more frequently cram them with much more food than is necessary; and besides these irregularities in regard to quantity, errors in the quality are not less fatal. A thin and bilious milk throws them into gripings of the bowels, and bilious diarrhoeas; and milk when too thick gives them fluxages or stoppages at the breast, and sometimes follicular catarrhs. And finally, the milk of a person, who has a remaining taint of the venereal disease, subjects the child to breakings-out, and ulcers of many kinds.

3. Motion and rest improperly managed are also the sources of many of the complaints of children. Nothing is more prejudicial to the health of a child than that frequent custom of idle nurses of rocking a child to

sleep, whether it will or not; the violent and continual motion in this case often gives the child a vertigo, which it never afterwards gets rid of.

The binding children too tight in their drest, is also another great cause of disorders, by obstructing the due motions of nature in the circulation of the blood. The forcing children too early on their feet, and compelling them to walk too early is also the cause of many mischiefs. And nothing is more mischievous than the frequent disturbing them out of their sleep: this makes them peevish, and torpid, and sleepy at other times.

4. The suppression of the natural excretions is also the origin of many disorders; and though this may sometimes happen from an innate cause in the infant, it much oftener is owing to the perverseness of the nurse in feeding on acid foods, or such as are hard of digestion; and exposing the child, as well as her own breasts to the cold air, when they are hot.

Infants, from the great tenderness of their parts, are much more subject to the severity of diseases than grown persons; yet experience shews us, that they usually get through them with less danger. An instance of this is evident in the small-pox, from which people in general escape much better when young than at any other time. Convulsions, violent hiccoughs, and fevers and almost continual crying, are almost every often to be fatal to children in the first six weeks; but are much less dangerous afterwards; and convulsions become habitual to children, though they are often very frequent in their returns upon every slight occasion, yet are found much less dangerous than in other cases. In general, all diseases come to a shorter period in infants than in grown persons.

Most of the distemperatures of children, in the first stage of infancy, arise chiefly from their bowels, and are to be cured by gentle correctives and evacuates; and of these the very mildest in their operation are always to be chosen. The use of gentle vomits is safe and proper. Five or six grains of the powder of ipecacuanha may be mixed in two table-spoonfuls of water, and sweetened with a little sugar; a tea-spoonful of this may be given every quarter of an hour till it operates. Or, a grain of emetic tartar may be dissolved in three ounces of water, sweetened with a little syrup, and given in the same manner. Or, six or seven drops of the antimonial wine may be administered in a tea-spoonful of water or this gruel. These medicines will cleanse the stomach, and, generally, open the belly; but if the child be colic, mucus and pulp of calia may be dissolved in boiling water, and given in small quantities till it operates; or a few grains of magnesia alba may be mixed in any kind of food, that is given to the child, and continued till it has the desired effect. Some have highly extolled the use of mercurius dulcis or calomel, given from one grain to three or four, as a purge for children, which have no fever, especially in cases of disorder arising from the retrospulsion of cutaneous humours; but others think this medicine should be used with great caution.

Manna, infusions of sena, and small doses of syrup of buck-thorn, may also be given as purges to children, where there is no fever joined with their complaints; but where there is a feverish disposition, rhubarb is to be preferred. In violent gripings and pains attended with crying out, tremors and tremblings, and acrid stools, mucilaginous medicines often prove of more service than the absorbents. Worms in infants, when alive in the bowels, often bring on atrophies and convulsions; and when dead and putrified, they occasion many malignant effects, with convulsions and often unaccountable symptoms. When alexipharmic or diuretic medicines are found necessary, it is always much better to give them to the nurse than to the child; but antimony-diaphoretic, when faithfully prepared, is a medicine of great power, and yet so safe that it may be given to the infant. Narcotic medicines are to be given with the utmost caution; a single grain of theriaca seems as proper as any thing for this purpose. Cannabar in small doses is found to be an excellent remedy in convulsions; but if it be given too freely, it generally loads the stomach. Junker and Buchan.

INFANTIL and *INFANTA*: are titles of honour given to the children of some princes; particularly those of the houses of Spain and Portugal.

It is usually said, that the appellation *infante* was introduced into Spain, on occasion of the marriage of Eleanor of England with King Ferdinand of Castile; and that their son Sancho was the first that bore it.—But this is contradicted by Pelagius bishop of Oviedo, who lived in the year 1100, and who informs us, that the titles *infante* and *infanta* were used in Spain ever since the reign of King Evermond II.

INFANTRY, the body of foot-soldiers, in an army, or other corp.

The *infantry* stand contradistinguished from the *cavalry*, or horse.

INFANTRY exercise. See EXERCISE.

INFARCTION of the liver. See HEPATIS infarctus.

INFARCTION of the spleen. See SPLEEN.

INFATUATE, to prepossess any one in favour of some person or thing that does not deserve it, so far as that he cannot easily be disabused.

The word *infatuate* comes from the Latin *infatuus*, *fat*: of *fari*, to speak out; which is borrowed from the Greek *φασι*, whence *paros*, which signifies the same with *paros* in Latin, or *prophet* in English: and the reason is: because their prophecies or oracles used to be seized with a kind of madness, or folly, when they began to make their predictions, or deliver oracles.

The Romans called those persons *infatuati*, *infatuati*, who fancied they had been visited, or imagined the god Faunus, whom they call *Parus*, had appeared to them.

INFECTIO, the catching a disease, by some effluvia, or fine particles, which fly off from disordered bodies, and mixing with the juices of others, occasion the same disorders as were in the bodies they came from.

The word comes from the Latin verb *inficere*, which properly signifies to dye of some other colour; *inficere*, I. c. *facere*, at aliud intus fit, to occasion something to be imbibed. See CONTAGION.

INFERNAL, in *Antiquity*, sacrifices offered to the diæmanes, or the souls of deceased heroes and illustrious persons; or even of any relation or person whose memory was held in veneration.

INFERNAL, stands opposed to SUPERIOR.

INFERIOR court of record, in *English Law-writers*, is used as a general name for corporation-courts, courts leet, and sheriffs-towns. See COURT.

Most courts are subordinate to some other; but for distinction sake the term *inferior-court* is by Sir Matthew Hale, and others, applied in the manner here mentioned.

INFERIOR metals, *ærea*, *plumbæ*. See the substantives.

INFERIOR penis, in *Anatomy*, a name given by Spigelius to one of the muscles of the penis, generally called the accelerator by the moderns; and by Vesalius, and others of his time, *primus penis*.

INFERIOR oblique, *ferratus*, *fuscapularis*. See the several articles.

INFERIORIS labii depressor, *labii elevator*. See DEPRESSOR, and ELEVATOR.

INFERNAL glass, in *Chemistry*, is a name given to the Bolt-head, when its vessel is continued downwards into the body of the glass vessel, and left open only by a very small orifice.

INFERNAL salt, a name given by Hoffman, and some other of the chemical writers, to nitre; they have also called it *carbæus chemicus*.

INTERNAL stone. See LAPIS infernalis, CAUSTIC and CRYSTALLA of silver.

INFERTILITY. See FERTILITY.

INFIBULATION, in *Antiquity*. It was a custom among the Romans, to infibulate their singing boys, in order to preserve their voices: for this operation which prevented their retracting the prepuce over the glans, and is the very reverse to circumcision, kept them from injuring their voices by premature and preposterous venery: serving as a kind of padlock, if not to their inclinations, at least to their abilities. It appears by some passages in Martial, that a less decent use was made of *infibulation* among the luxurious Romans: for some ladies of distinction, it seems, took this method of confining their paramours to their own embraces. Juvenal also hints at some such practice. Celsus, a chaste author, says, *infibulation* was sometimes practised for the sake of health; and nothing destroys it more than the silly practice this operation seems intended to prevent. This practice is not perhaps likely to be revived; if however any one who has suffered in his constitution by preposterous venery, should be able to get children, and should be inclined to prevent the same misfortune in them, by *infibulation*; the method of doing it is thus:

The skin which is above the glans is to be extended, and marked on both sides with ink, where it is perforated, and then suffered to retract itself. If the marks recur upon the glans, too much of the skin has been taken up, and we must make the marks farther; if the glans remain free from them, they show the proper place for affixing a *fibula*: then pass a needle and thread through the skin where the marks are, and tie the threads together; taking care to move it every day, until the parts about the perforations are cicatrized: this being effected take out the thread, and put in the *fibula*; which the lighter it is the better. Celsus, lib. vii. cap. 25.

Authors have not determined what the *FIBULA* of the

ancient surgeons was, though no doubt they were for different purposes. In the present case, the *fibula* seems to mean a ring of metal, not unlike what the country people put through the noses of swine.

INFIDEL, a term applied to such persons as are not baptized and that do not believe the truths of the Christian religion. See DEIST.

INFINITE, that which has neither beginning, nor end: in which sense God alone is *infinite*.

INFINITE is also used to signify that which has had a beginning, but will have no end: as angels, and human souls.

This makes what the schoolmen call *infinitum a parte post*; as, on the contrary, by *infinitum a parte ante*, they mean that which has an end, but had no beginning. See INDEFINITE and FINITE.

INFINITE, in *Mathematics*, is applied to quantities which are either greater, or smaller, than any assignable ones. In which sense it differs not much from what we otherwise call *indefinite*, or *indeterminate* numbers. Thus, an *INFINITE*, or *INFINITELY great* line, in geometry, denotes only an indefinite or indeterminate line; to which no certain bounds, or limits, are prescribed.

INFINITE quantities. Though the idea of magnitude infinitely great, or such as exceeds any assignable quantity, does include a negation of limits; yet all such magnitudes are not equal among themselves; but besides *infinite* length, and *infinite* area, there are no less than three several sorts of *infinite* solidity: all of which are quantities *vis generis*; and those of each species are in given proportions.

Infinite length, or a line infinitely long, is to be considered, either as beginning at a point, and so infinitely extended one way; or else both ways from the same point: in which case the one, which is a beginning of infinity, is one half of the whole, which is the sum of the beginning and ceasing *infinity*, or, *infinity a parte ante*, and a *parte post*, which is analogous to eternity in time or duration; in which there is always as much to follow, as is past any point or moment of time.

Nor does the addition or subtraction of time, length or space of time, alter the case, either as to infinity or eternity; since neither the one nor the other can be any part of the whole.

As to infinite surface or area, any right line infinitely extended both ways on an *infinite* plane, divides that plane into equal parts, the one to the right, and the other to the left of the said line; but if from any point in such a plane, two right lines be infinitely extended, so as to make an angle; the *infinite* area, intercepted between these *infinite* right lines, is to the whole *infinite* plane, as the arch of a circle drawn on the point of concurrence of those lines as a centre, intercepted between the said lines, is to the circumference of the circle; or as the degrees of the angle to the 360 degrees of a circle.

For an example—Two *infinite* right lines meeting at a right angle on an *infinite* plane, do include a quarter part of the whole *infinite* area of such a plane: if two parallel *infinite* lines be supposed drawn on such an *infinite* plane, the area intercepted between them will be likewise *infinite*; but at the same time it will be infinitely less than the space intercepted between two *infinite* lines, that are inclined, though with never so small an angle, because in the one case the given *finite* distance of the parallel lines diminishes the infinity in one degree of dimension; whereas in the other, there is infinity in both dimensions; and consequently the quantities are one infinitely greater than the other, and there is no proportion between them.

From the same consideration arise three several species of *infinite* space or solidity; for a parallelepiped, or a cylinder infinitely long, is greater than any *finite* magnitude, how great soever; all such solids supposed to be formed on a given basis, are in proportion to one another, as those bases. But if two of those three dimensions are wanting, as in the space intercepted between two parallel planes infinitely extended, and at a finite distance; or with infinite length and breadth, it has a finite thickness; all such solids shall be as the given finite distances one to another.

But these quantities, though infinitely greater than the other, are yet infinitely less than any of those wherein all the three dimensions are *infinite*—Such are the spaces intercepted between two inclined planes infinitely extended; the space intercepted by the surface of a cone, or the sides of a pyramid, likewise infinitely continued, &c. of all which, notwithstanding the proportions of one to another, and to the *vis vis*, or vast abyss of *infinite* space (wherein is the focus of all things that are, or can be) or to the solid of *infinite* length, breadth, and thickness (taken all manner of ways) are easily assignable—For the space between two planes is to the whole, as the angle

angle of those planes to the 360 degrees of the circle. As for cones and pyramids, they are as the spherical surface intercepted by them, is to the surface of the sphere; and therefore cones are as the versed lines of half their angles, to the diameter of the circle: these three sorts of *infinite* quantity are analogous to a line, surface, and solid: and, like them, cannot be computed or have any proportion one to another.

INFINITE, *Arithmetic of*. See **ARITHMETIC**.

INFINITE, *Characters in arithmetic of*. See **CHARACTER**.

INFINITE, *Decimals*. See **REPTEND**.

INFINITE, *Propositions in Logic*. See **PROPOSITION**.

INFINITE, *Diffs. in Law*. See **DISTRESS**.

INFINITELY *small quantity*, called also an *infinitesimal*, is that which is so very minute, as to be incomparable to any finite quantity; or it is that which is less than any assignable quantity.

An *infinite* quantity cannot be either augmented, or lessened, by adding or taking from it any finite quantity; neither can a finite quantity be either augmented, or lessened, by adding to, or taking from it an *infinitely small* quantity.

If there be four proportionals, and the first be *infinitely* greater than the second, the third will be *infinitely* greater than the fourth.

If a finite quantity be divided by an *infinitely small* one, the quotient will be an *infinitely great* one; and if a finite quantity be multiplied by an *infinitely small* one, the product will be an *infinitely small* one; if by an *infinitely great* one, the product will be a finite quantity.

If an *infinitely small* quantity be multiplied into an *infinitely great* one, the product will be a finite quantity.

In the method of infinitesimals, or of *infinitely small* quantities, the element by which any quantity increases or decreases, is supposed to be *infinitely small*, and is generally expressed by two or more terms; some of which are *infinitely less* than the rest, which being neglected as of no importance, the remaining terms form what is called the difference of the proposed quantity. The terms that are neglected in this manner, as *infinitely less* than the other terms of the element, are the very same which arise in consequence of the acceleration, or retardation, of the generating motion, during the *infinitely small* time in which the element is generated; so that the remaining terms express the element that would have been produced in that time, if the generating motion had continued uniform, as is farther explained under **FLUXION**.

Therefore those differences are accurately in the same ratio to each other, as the generating motions or fluxions. And hence, though infinitesimal parts of the elements are neglected, the conclusions are accurately true, without even an *infinitely small* error, and agree precisely with those that are deduced by the method of fluxions. In order to render the application of this method easy, some analogous principles are admitted, as that the *infinitely small* elements of a curve are right lines, or that a circle is a polygon of an infinite number of sides, which being produced give the tangents of the curve, and by their inclination to each other measure the curvature. This is as if we should suppose that when the base flows uniformly, the ordinate flows with a motion which is uniform for every *infinitely small* part of time; and increases, or decreases, by *infinitely small* differences at the end of every such time.

But however convenient this principle may be, it must be applied with caution and art, on various occasions. It is usual therefore, in many cases, to resolve the element of the curve into two or more *infinitely small* right lines; and sometimes it is necessary (if we would avoid error) to resolve it into an infinite number of such right lines, which are infinitesimals of the second order. In general it is a *postulatum* in this method, that we may descend to infinitesimals of any order whatever, as we find it necessary; by which means any error that might arise in the application of it, may be discovered and corrected by a proper use of this method itself.

It is also to be observed, that when the value of a quantity that is required in a philosophical problem becomes in certain particular cases *infinitely great*, or *infinitely little*, the solution would not be always just, though such magnitudes were admitted. As when it is required, to find by what centripetal force a curve could be described about a fixed point that is either in a curve, or is so situated that a tangent may be drawn from it to the curve. The value of the force is found *infinite* at the centre of the forces in the former case, and at the point of contact in the latter: yet it is obvious, that an *infinite* force could not deflect the line described by a body that should proceed from either of these points, into a curve; because the direction of its motion in either case passes through the centre of the forces, and no

force how great soever that tends towards the centre could cause it to change that direction. But it is to be observed, that the geometrical magnitude by which the force is measured is no more imaginary in this than in other cases, where it becomes *infinite*; and philosophical problems have limitations that enter not always into the general solution given by geometry.

But although by proper care errors may be avoided in the method of infinitesimals, yet it must be owned that to such who have been accustomed to a more strict and rigid kind of demonstration in the elementary parts of geometry, it may not seem to be consistent with perfect accuracy, that, in determining the first differences, any part of the element of the variable quantity should be rejected, merely because it is *infinitely less* than the rest; and that the same part should be afterwards employed for determining the second and higher differences, and resolving some of the most important problems. Nor can we suppose, that their scruples will be removed, but rather confirmed, when they come to consider what has been advanced by some of the most celebrated writers on this method, who have expressed their sentiments concerning *infinitely small* quantities in the precise terms; while some of them deny their reality, and consider them only as incomparably less than finite quantities, in the same manner as a grain of sand is incomparably less than the whole earth; and others respect them, in all their orders, as no less real than finite quantities. And although it appears from what has been said in this article, that a satisfactory account may be given for the brief way of reasoning that is used in the method of infinitesimals; while nothing is neglected without accounting for it; and that the harmony between the method of fluxions and that of infinitesimals thus appears more perfect.

And however safe and convenient this method may be, yet some will always scruple to admit *infinitely little* quantities, and *infinitely orders* of infinitesimals, into a science that boasts of the most evident and accurate principles, as well as of the most rigid demonstrations. It is therefore proper, that this extensive and useful doctrine should be established on unexceptionable principles. See the articles **FLUXION**, and **LIMIT**. See also **Mr. MacLaurin's Treat. of Fluxions** in the introduction, p. 394, 40, &c. and book i. art. 495 to 502.

INFINITELY *Infinitesimal Fractions*, or all the powers of all the fractions whose numerators are one, are together equal to an unit. See the demonstration heretofore given by Dr. Wood, in Hooke, Phil. Coll. N^o 3. p. 45. seq. Hence, it is deduced, 1^o, That there are not only *infinite* progressions, or progressions in *infinitum*; but also *infinitely* farther than one kind of infinity. 2^o, That the *infinitely infinite* progressions are notwithstanding computable, and to be brought into our sum; and that not only finite, but so small as to be less than any assignable number. 3^o, That of *infinite* quantities, some are equal, others unequal. 4^o, That one *infinite* quantity may be equal to two, three, or more other quantities, whether *infinite* or finite.

INFINITE, *Verbs*. See **SERIES**.

INFINITIVE, in Grammar, the name of one of the MOODES, which serve for the conjugating of verbs.

The *infinitive* does not denote any precise time, nor does it determine the number, or persons, but expresses things in a loose indefinite manner; as, *to teach*, &c.

Hence the Latin and modern grammarians have called verbs under this mode, from their indefinite nature, *infinitives*. Sanctius has given them the name of impersonals; and the Greeks that of *anaprositos* from the same reason of their not discovering either person or number.

Infinitives, says Mr. Harris, not only lay aside the character of ATTRIBUTIVES, but they also assume that of **EXEGETIVES**, and are distinguished with their several attributes: e.g. *Dulce & decorum est pro patria mori*; *scire tuum nihil est*, &c.

Hence the *infinitive* has been sometimes called *verbum passivum*, a verbal noun; sometimes *verbum passivum*, the verb's noun. The reason of the appellation is evident in Greek, by its taking the prepositional article before it in all cases; thus, *το γινωσκον, το γινωσκον, το γινωσκον*. The same construction is not unknown in English. Thus Spencer,

For not to have been dipped in Lethe's lake
Could save the soul of Thetis from to die &c.

NOT TO BE.

The Stoics held the *infinitive* as the genuine *forma* or verb, a name which they denied to all other modes, because the true verbal character was conceived to be contained simple and unmixed in the *infinitive* only; thus, *to walk*, means simply that energy, and nothing more: the other modes,

besides expelling this energy, supersedes certain affections, which respect persons and circumstances. The *infinitive*, says Priscian, *significat ipsam rem, quam continet verbum*. The *infinitive*, in the application of it, naturally coalesces with all those verbs, that denote any tendency, desire, or volition of the soul, but not readily with others. See Harris's *Hermes*, p. 163, &c.

In most languages, both ancient and modern, the *infinitive* is distinguished by a termination peculiar to it; as *verbum* in the Greek, *verbo* in the Latin, *verbe* in the French, *verbo* in the Italian, &c. but the English is defective in this point; so that to denote the *infinitive*, we are obliged to have recourse to the article *is*; excepting sometimes when two or more *infinitives* follow each other.

The practice of using a number of *infinitives* successively, is a great but a common fault in language; as, *he offered to go to teach to write English*.—Indeed, where the *infinitives* have no dependence on each other, they may be used elegantly enough; as *to murder, is to fight, is to sin, is to sin, to die*.

INFINITO, in the Italian Music, is used for such canon or fugues, as may be begun again and again: whence they are also called *perpetual fugues*. See **FIGURA**.

INFINITY, the quality which denominates a thing *infinitum*.

The idea signified by the name *infinity* is best examined by considering to what things *infinity* is by the mind attributed, and how the idea itself is framed: finite and infinite are looked upon as the modes of quantity, and are attributed primarily to things that have parts, and are capable of increase or diminution, by the addition or subtraction of any least part. Such are the ideas of space, duration, and number. When we apply this idea to the Supreme Being, we do it primarily in respect of his duration and ubiquity: and more figuratively, when to his wisdom, power, goodness, and other attributes, which are properly inexhaustible and incomprehensible: for when we call them *infinity*, we have no other idea of this *infinity*, but what carries with it some reflection on the number, or the extent, of the acts or objects of God's power and wisdom, which can never be supposed to great, or so many, that these attributes will not always surmount and exceed, though we multiply them in our thoughts with the *infinity* of endless number. We do not pretend to say, how these attributes are in God, who is infinitely beyond the reach of our narrow capacities: but this is our way of conceiving them, and these are our ideas of their *infinity*.

We come by the idea of *infinity* thus: every one that has any idea of any fixed length of space, as a foot, yard, &c. finds that he can repeat that idea, and join it to another, to a third, and so on, without ever coming to an end of his additions. From this power of enlarging his idea of space, he takes the idea of infinite space, or immensity. By the same power of repeating the idea of any length or duration we have in our minds, with all the endless addition of number, we also come by the idea of eternity.

If our idea of *infinity* be got by repeating without end our own ideas, it may be asked, why do we not attribute it to other ideas, as well as those of space and duration; since they may be as easily, and as often repeated in our minds, as the other? yet nobody ever thinks of infinite sweetness, or whiteness, though he can repeat the idea of sweet or white, as frequently as those of yard or day? To this it is answered, that those ideas which have parts, and are capable of increase by the addition of any parts, afford us by their repetition an idea of *infinity*, because with the endless repetition there is connected an enlargement, of which there is no end: but it is not so in other ideas; for it to the perfect idea I have of white, I add another of equal whiteness, it enlarges not my idea at all. Those ideas, which consist not of parts, cannot be augmented in what proportion men please, or be stretched beyond what they have received by their senses; but space, duration, and number, being capable of increase by repetition, leave in the mind an idea of an endless room for more; and so those ideas alone lead the mind towards the thought of *infinity*.

We are carefully to distinguish between the idea of the *infinity* of space, and the idea of a space infinite. The first is nothing but a supposed endless progression of the mind over any repeated idea of space; but to have actually in the mind the idea of a space infinite, is to suppose the mind already passed over all those repeated ideas of space, which an endless repetition can never totally represent to it; which carries in it a plain contradiction. See **SPACE**.

This will be plainer, if we consider *infinity* in numbers: the *infinity* of numbers, to the end of whose addition every one perceives there is no approach, easily appears to any one that reflects on it: but how clear soever this

idea of the *infinity* of numbers be, there is nothing yet more evident than the absurdity of the idea of an actual infinite number. Locke's *Essay*, vol. I. chap. xvii.

INFINITY of action, in Law; the lord of the soil may have a special action against him who shall dig soil in the king's highway: but one subject may not have his action against another for common nuisances; for if he might, then every man might have it, and so the *action* would be *infinitum*, &c. 1 Co. Inst. 56. q. Rep. 113.

INFIRMARY, a place where the sick and weak belonging to any society, or community, are disposed, either for nursing or cure. See **HOSPITAL**.

INFLAMMABILITY is that property of bodies which disposes them to kindle, or catch fire. See **FLAME**, **HEAT**, and **PHLOGISTON**.

INFLAMMABILITY of oils with acids. Among the many surprising phenomena which the world owes to the late improvements in chemistry, there is none which has more attracted the admiration of the generality of mankind than that remarkable one of producing actual flame by mixing two liquors, both cold to the touch: the acid spirits of minerals, and the chemical oil of vegetables. See **COMBUSTION**.

Becher is the first author who has published an account of this phenomenon. He observes, in his *Physica Subterranea*, that oil of vitriol which is a very strong acid liquor, with oil of turpentine which is a very sulphureous one, produces a violent heat, and actual fire or flame. Becher giving no farther account of the process than this, several of the succeeding chemists tried the experiment, but all without success. At length Borrichius (see Copenhagen Transactions for the year 1671) explained it, with all the necessary particulars, and the effect according to his directions has been sometimes produced; though the great uncertainty of a thousand little accidents, all of which must necessarily concur to the producing the flame, has made it often miss even in the most careful hands. The method of Borrichius is this: mix in a glass vessel four ounces of fresh drawn and highly rectified oil of turpentine, with six ounces of aqua fortis newly made and carefully prepared, cover the vessel, and shake the two liquors well together. After they have stood together half an hour, open the vessel, and there will proceed out of the mouth of it large quantities of flame mixed with great clouds of smoke. The experiment will not succeed, however, unless the liquors are fresh made, and the vessel be exposed to the heat of the sun. And many who have failed in trying the experiment, from their neglect of certain circumstances which appeared trifling to them, have censured both authors as relating untruths. Tournefort, in the year 1700, inflamed by this method the oil of salisæ. Homberg, in the year 1704, says, in the *Memoirs of the Academy*, that he inflamed oil of turpentine by mixing it with vitriolic acid; but he says, that the oil must be thick. Rouviere, in the year 1706, inflamed the empyreumatic oil of guayac; and his experiment was much talked of, because it succeeded more easily than the others, because this inflammation is very vivid, and because it is attended by a surprising circumstance, namely, that from amidst the flames arises a black, thin, spongy body, of a considerable height, which is, as we shall see, only the thickest part of the oil rarefied and burnt during the inflammation. This inflammation of oil of guayac was solely attended to, and was shewn to students in courses of chemistry and experimental philosophy: till Hoffman, a German chemist, and Geoffroy, a French chemist, having made many experiments on this matter, discovered at the same time, that smoking vitriolic acid, mixed with concentrated vitriolic acid, succeeded much better for the inflammation of oils, and particularly of the oil of turpentine, which had been almost relinquished. Mem. Acad. Paris. 1702, and 1706.

Mr. Rouelle then resumed this subject, and published, in the year 1747, a memoir filled with many experiments, which shewed, that by nitrous acid may be inflamed all essential oils, including oil of turpentine, and even those sweet expressed oils which are capable of quickly thickening and drying, such as oils of nuts, linseed, hemp, provided that the acid be sufficiently concentrated. Lastly, the same chemist discovered, that even the sweetest oils least disposed to dry, that is, those called *fat oils*, may also be inflamed. But to make their inflammation succeed, the method mentioned by Hoffman and Geoffroy was necessary: that is to say, some concentrated vitriolic acid must be previously mixed with the nitrous acid. As these last mentioned oils are of all oils the least inflammable, we have reason to believe that every oil may be inflamed by a mixture of these two acids.

Mr. Rouelle further remarks, in the above quoted memoir, that flame is more certainly produced in all these

experiments, when the nitrous acid is poured on at intervals, and when it is applied to that part of the oil which the portions of acid had poured on had thickened, heated, and dried. The inflammation of oils by acids is now become an experiment easily performed. The following circumstances are remarked to be peculiar to the inflammation of the several kinds of oil.

All essential oils, and even the sweet drying oils, may be inflamed by the nitrous acid alone, provided that the vessel in which the inflammation is to be made be of a convenient size and form, that the nitrous acid be sufficiently concentrated, and that a sufficient quantity of acid and oil be employed. The vessel ought to be sufficiently wide-mouthed; and the nitrous acid, for greater certainty, ought to be so concentrated that a phial, capable of containing exactly an ounce of pure water, shall be capable of containing one ounce, four grains, and two scruples of this acid. Lastly, an ounce of this acid, and as much of the oil to be inflamed, ought to be employed, although less quantities may succeed, but less certainly. The oil is first put into the vessel in which the inflammation is intended to be. Then the vessel containing the nitrous acid is to be tied to one end of a rod, that the operator may not be hurt by the part of the mixture which is generally thrown out of the vessel, and sometimes to a considerable distance. One half or two-thirds of the acid is poured at once. A considerable ebullition is excited by the reaction of these two liquids. The oil becomes black, thick, and sometimes indurated. If it does not inflame within four or five seconds, more nitrous acid must be poured upon the part which appears thickest and driest, and then the mixture never fails to be inflamed.

The oils of almonds, olives, rapes, and other fat oils, have not been hitherto inflamed by the nitrous acid alone. But their inflammation is excited, as Mr. Rouelle practices, by mixing with them first equal quantities of the concentrated vitriolic and nitrous acids, which occasion less quick and violent ebullition than in the preceding instances; but when this ebullition is at its height, some pure nitrous acid must be poured on the thickest part of the mixture. Then the inflammation generally happens, but it is less strong than when any other kind of oil is used. Although these phenomena be surprising, their theory is easy. All oils contain phlogiston as a constituent part. Nitrous acid also contains phlogiston. Hence we may understand the cause of the powerful action of these two substances upon each other. The heat resulting from their reaction is equal to that of ignition; and hence the oil and even the nitrous acid being capable of inflammation, must consequently be inflamed. Chemical Dict. vol. ii. art. *Inflammation*.

INFLAMMABLE principles. See PHLOGISTON.

INFLAMMATION, from *in*, and *flamma*, flame, in *Surgery* and *Physic*, a tumor attended with a preternatural heat, and redness, and a continual pulsation and pricking; frequently arising from some obstruction or stagnation in the small arterial blood-vessels or lymphatics; by means whereof the blood flowing into some part faster than it can run off again, swells up, and causes a tension, with an unusual fulness, redness, and heat.

Others have defined *inflammation*, in relation to the cause that produces it, to be an increased circulation in any part, from irritation, external or internal, local or universal: in consequence of which irritation, a greater quantity of fluid circulates through, and is secreted in a part that is inflamed, than when it is in its natural state. However, nothing has been more variously accounted for than the proximate cause of *inflammation*; and in all probability, says an ingenious writer, it is intimately connected with those operations of the minute parts of the body which we are at present, and perhaps shall ever remain, ignorant of. The symptoms of every *inflammation*, which are a painful tumor, with increased heat, redness, and sensibility, plainly shew a congestion of fluids, a more frequent action of the moving power, and a violent state of the nerves disposing them to communicate sensation in too great a degree. The remote causes of *inflammation* are wounds, bruises, sudden and excessive colds, luxations, aromatic stimulents, &c. Physicians have given distinct names to the *inflammations* of several parts; see the subsequent articles. All the *inflammations* that are denominated phlegmonous are seated in the sanguine arteries of the part inflamed; and the mucous membrane is the seat of those *inflammations* which are distinguished by the name of *inflammations* of the mucous membrane; in which case, the irritation being in the surface of the membrane, stimulates the secretory mucous glands to accumulate and discharge more than they do in a natural state. If there are tumors, the *inflammation* is phlegmonous; and these are distinguished into phlegmonous which are seated in the

sanguine arteries and cellular membrane (see PHLEGMON); and erysipelatos, whose seat is in the skin, or other internal membranes not cellular. See ERYSIPELAS.

Inflammations terminate variously according to their different degrees of violence, the causes from which they arise, the parts which they affect, and the particular constitution of the patient, with several other circumstances that preface what will be the end of the *inflammation*. But the several ways wherein an *inflammation* terminates have been usually reckoned four. The first is resolution; when, upon removing the cause, the symptoms go off gradually, and leave the part in the same state in which it was before the disease took place. This is the termination which is always to be preferred, unless the *inflammation* has been produced by morbid matter, which is to be discharged externally.

The grand intention of the treatment of all *inflammations* should be to open such small vessels as are obstructed, and to restore the blood to its natural confidence and free circulation; and this is commonly termed in surgery the resolution or dispersion of tumors. When in cases of this kind the *inflammatory* signs are but gentle, it is always best immediately to set about the dispersing of the tumor. If the cause of the *inflammation* is external and obvious, as thorns, splinters, bullets, or any other foreign body stuck in the part, this is to be immediately removed, if that can be done with safety. So when the *inflammation* proceeds from too tight a bandage in wounds, &c. or from a luxation or fracture, the first thing to be done is to loosen the bandage, to set the fracture, or to reduce the luxation. It is after this very proper to open a vein in the arm, and after that to give a brisk but not heating purge; and if the symptoms do not abate, this method is to be repeated at proper intervals. Internal medicines which are watery, diluting, cooling, and strengthening, do great service on these occasions.

A proper regimen is also to be observed in regard to diet: all aliments that are of difficult digestion, all pickled or salted meats, and all spices and fermented liquors, with every thing else that may tend to heat and inflame the blood, are to be carefully avoided. The most proper aliments are broths, and drinks made of pearl-barley, oats, or flour. Decoctions of all the cooling plants, as sorrel, endive, &c. mixed with small quantities of lemon-juice, or any other of the vegetable acids, are useful; and when the *inflammation* is great, a little nitre should be added to the drinks. Nor is there less care required about the external applications; for though some to appease *inflammations* use only heating medicines, and others only cooling ones, yet either sort, if applied at random, and in all cases, may prove pernicious; for one medicine can never in these cases serve for all constitutions. To persons of a hot temperament the cooling external remedies are in these cases to be applied. Of this kind are the litharge-vinegar, applied warm on linen rags folded together, or hot vinegar mixed with red-lead, or with bole armeniac, and applied in the same manner; or oxyrate, or vinegar, and water mixed in equal quantities; or of any of these liquors may be taken six ounces, and to this an ounce of common salt, and two ounces of either nitre or sal ammoniac being added, and with this mixture linen rags many times doubled, and applied wet to the part, will be of great service. In the night-time also, when these applications cannot so conveniently be renewed, a plaster of the red-lead, or other cooling one, may be of no small use. This is the proper method in hot constitutions; but, on the contrary, in cold and phlegmatic ones, spirit of wine alone, or camphorated spirit, or either of these with an admixture of a small quantity of Venice treacle, are very successful remedies for the dispersion of *inflammations*, being applied on linen cloths doubled in the same manner; also is spirit of wine mixed with lime-water, or even lime-water alone, or Hungary water with spirit calaminaris, ceruse, (al) umbratilis, or bole armeniac, or a mixture of a pint of rectified spirit of wine with two ounces of Castile soap. This last applied warm is hardly second to any medicine in these intentions. Decoctions of wormwood, mint, fennel, southernwood, and other such herbs, made with salt-water or lime-water, are also very good external applications; and to these may be added, when necessary, either camphorated spirit of wine, or Castile soap; and not only the decoction of these herbs, but the herbs themselves when boiled may be applied as a cataplasm, with great success.

Mr. Goulard observes, that emollient topics are in great measure contrary to the indications that are to be fulfilled in resolving an *inflammation*: they increase every degree of tumor, by adding to the quantity of accumulated matter, and rendering the vessels more yielding

to its impulse and less able to carry it off. Saturnine topics, on the other hand, seem peculiarly calculated to answer every indication of a resolvable inflammation. The astringent and sedative properties combined, tend to give a tone to the fibres, and make the vessels capable of emptying themselves, and at the same time to moderate the increased motion and tension. Other astringents and stimulant, such as the usual mixture of vinous spirit with vinegar, will likewise prove sedative. The saturnine water, by its mild astringency, its sedative and antiseptic quality, seems peculiarly adapted to that species of inflammation called the ERYSIPELAS. However, there are various cases in which the resolution of an inflammation cannot possibly be effected; and, therefore, in such cases, recourse must be had to such means as are most likely to promote a speedy and favourable suppuration, which is the second mode in which an inflammation terminates, or rather the consequence of it. 3. An inflammation sometimes terminates in EPHACELE or GANGRENE, which is produced by a putrefaction generated in the mortified parts, and communicating its ferment to the surrounding parts. This should never be promoted by art, but its progress prevented or limited by separation of the dead flesh, or checking the purgative fermentation in it. For this purpose, emollients, with a proper mixture of antiseptics, should be used; practice has, therefore, rightly introduced the application of warm poultices, composed of farinaceous substances and vinegar, strong beer grounds and the like; and the caustic made of saturnine water appears very well calculated for this purpose. But when a spreading gangrene proceeds from an internal cause, which usually happens in dyspeptic and leucophlegmatic habits, or in extreme old age, emollients of every kind are to be avoided, and the warmest stimulants and most powerful antiseptics are indicated. The fourth mode in which an inflammation terminates, according to some writers, is a SCIRRUS, which grows more compact in the part affected, as the inflammation remits or goes off. But this is justly considered by some late writers as a peculiar disease; since it seldom or never occurs but in venereal, scrophulous or cancerous cases, when it is the forerunner, and not the consequence of an inflammation; the tumor generally appearing before the discoloration.

It may be observed, in general, that in all phlegmonous inflammations, there are two indications, viz. to lessen or remove the irritation, and to abate the increased afflux of the humours. With respect to the first, endeavours must be used to remove every thing that occasions the morbid irritation: when spasms are the cause, opium is the most proper remedy; when a stimulating fluid is secreted on a sensible membrane, its action may be hindered by the application of oily, unctuous, or mucilaginous matter: the morbid acrimony may be destroyed by proper alteratives, as mercury, &c. the irritability of the part may be destroyed or diminished by means of the bark, preparations of lead, &c. The distention of the internal vessels may be rectified, by restoring the circulation on the external surface of the body, or giving internal medicines to relax the small vessels, through the system, by their action on the stomach, such as nitre, sal ammoniac, all the neutral salts, specuacina, fenicearoot, antimonial preparations, cold water, by external applications, as fomentations, blisters, &c. The second indication may be answered by bleeding, purging with neutral salts, internal sedative medicines, as acids and narcotics, and the external application of sedatives, as the preparations of lead, &c. An inflammation may also be excited on the skin, if it be not the part inflamed, near the part primarily affected, by means of friction, the volatile liniment or blister, the diet should be cooling and attenuating, as already directed; and the only salutary water, in which gum arabic has been dissolved, with the addition of nitre. The belly should be kept lax in all kinds of inflammation, and internal ones are much relieved by a frequent use of clysters. Vapours and warm baths serve to lessen the irritation of the fibres and to retard the motion of the blood. When the inflammation abates, antiseptics and aperients, such as guaiacum, iuliasars, &c. are used with some advantage. Heister's Surgery, part i. p. 194. &c. Aikin on Lead, &c. p. 39. Motherby's Diet art. Inflammation.

A late author is of opinion that the ophthalmia, angina, pharyngitis, peripneumonia, pleuritis, hepatitis, nephritis and rheumatism, have all the same characteristics, and differ in nothing but the part affected; so that if one has a right knowledge of an inflammation on an external part, its progress and proper remedies, and at the same time is thoroughly acquainted with anatomy and the animal economy, he cannot be at a loss to distinguish and treat any of the diseases belonging to this class. Medic. Edinb. vol. i.

INFLAMMATION of the bladder proceeds, in a great measure, from the same causes as that of the kidney, and requires a similar treatment. It is known by an acute pain towards the bottom of the belly, and difficulty of passing urine, with some degree of fever, a constant inclination to go to stool, and a perpetual desire to make water. The diet must be light and thin, and the drink of a cooling nature. Bleeding is very proper at the beginning, and in robust constitutions it will often be necessary to repeat it. The lower part of the belly should be fomented with warm water, or a decoction of mild vegetables, and emollient clysters ought frequently to be administered, &c. the patient should abstain from every thing that is of a hot, acid, and stimulating quality, and live entirely upon small broths, gruels, and mild vegetables. Buchan.

INFLAMMATION of the pleura. See PLEURISY.

INFLAMMATION of the spleen. See SPLEENITIS.

INFLAMMATION of the stomach, called also, gastritis and inflammatory colic, proceeds from any of the causes which produce an inflammatory fever, as cold liquor drunk when the body is warm, obstructed perspiration, or the sudden striking in of an eructum; or, from the acrimony of the bile, and acid substances taken into the stomach, as strong vomits or purges, corrosive poisons, &c. It is also occasioned by rejecting the goat from the extremities; and by hard indigestible substances, as bones, the bones of fruit, &c. swallowed into the stomach. This disease is attended with a fixed pain and burning heat in the stomach; great restlessness and anxiety; a small, quick, hard pulse; vomiting, or at least a nausea and sickness; excessive thirst; coldness of the extremities; difficulty of breathing; cold clammy sweats; and sometimes convulsions and fainting fits. The stomach is swelled and feels hard to the touch; and the patient has a sense of pain when he takes any kind of food or drink, especially if it be either too hot or cold. When he vomits every thing he eats or drinks, is extremely restless, has a hiccup, with an intermitting pulse and frequent fainting fits, the danger is very great.

In this disorder all acrimonious, heating, and irritating food and drink are to be carefully avoided: and a vomit is very hurtful. The food should be light, thin, cool and easy of digestion; the drink should be clear whey, barley water, or decoctions of emollient vegetables, as liquorice and marsh-mallow roots, farsaparilla, &c. Bleeding is almost the only dependence, and it must be freely used, notwithstanding the towniness of the pulse, and repeated till the pulse rises. Flannel cloths dipped in lukewarm water, or a decoction of emollient vegetables, should be applied to the region of the stomach. The feet and legs ought to be frequently bathed in lukewarm water, and warm bricks or poultices applied to the soles of the feet. The warm bath is also very beneficial. In this, and all other inflammations of the bowels, an emollient, or blistering plaster, applied over the part affected, is an excellent remedy, and seldom fails of giving relief. Mild clysters of warm water, or thin water gruel, with the addition of a little sweet oil, honey, or menna, when the patient is collic, should be frequently administered, and are of very great importance. Buchan's Dom. Med. p. 314, &c.

INFLAMMATION of the throat. See ANGINA and QUINZY.

INFLAMMATION of the tongue. See TONSILL.

INFLAMMATION of the vagina. See VAGINA.

INFLAMMATION of the womb is a disorder to which women after child-birth, when the LOCHIA are impeded, are most frequently subject: the common causes of this complaint, besides those of internal inflammation in general, are tearing, bruising, external stimuli, and obstructed menstrus or lochia. When it happens after abortion and child-birth, it is attended with a pain at the bottom of the belly, which is neither throbbing nor constantly acute; a frequent pulse, often small, sometimes irregular, and in strong habits and after early abortions, hard; a delirium

a delirium, subsistens tendinum, and other symptoms of irritation: the womb gangrenous and mortified, and the patient sunk. But if the uterus has not been lately impregnated, the pain is more constant, bounded and throbbing: the pulse is hard, full, and strong, and accompanied with other symptoms of general inflammation; and if the disease increases, the pulse is small and frequent, the symptoms of irritation attend, and supuration is more likely to happen. In both, as different parts of the womb are affected, there is a strangury or a supposition of urine: the small quantity discharged is fetid and hot; a tenesmus attends with a pain in going to stool; or, there is pain in moving the lower extremities, or swelling, with heat, to be felt by introducing a finger up the vagina, the os tunic being shut; universal restlessness, thick urine, pain upon external pressure; the belly is tense, a red stain extends up to the navel and tenses black when fatal; and if it happens in an impregnated uterus, an abortion follows. It often happens that the woman can only lie on her back, and on turning to either side, she feels a painful heavy mass fall to that side, and at the same time an excessive pain in the loins, kidneys, and groin of the opposite side. This disorder may be removed by a spontaneous eruption of the menses, or of the lochia, or, after an abortion or childbirth, by a constant, gentle, and long continued sweat; or, it may terminate in an abscess or a mortification, both which are almost always fatal. When an inflammation attacks a womb not lately impregnated, the common remedies used in cases of internal inflammation are to be employed. In abortions and labours, when the patient hath not been much weakened, and the pulse is hard and not very frequent, bleeding in the arm may be beneficial, but can rarely be repeated: therefore the general method of cure will depend on relaxants, such as the antispasmodic powder and saline draught, moderately used. To which may be added anodyne and antispasmodic fomentations and poultices. Perspiration may be free; the other usual evacuations by urine and stool may be moderately promoted; but all extraordinary ones are dangerous. If the pain continues, notwithstanding the usual treatment, opiate may be sometimes given with success. If a supuration comes on, an exit for the pus should be procured as soon as possible, which, when it points to the perineum, may be sometimes obtained. Motherly.

INFLAMMATORY diseases. To these are to be referred coughs, pleuritis, peripneumonies, acute rheumatisms, inflammations of the brain, bowels, and other parts, attended with a fever; also lesser inflammations without a fever, and fevers of an inflammatory kind, where no part is so peculiarly affected as to give name to the disease. And, lastly, all chronic disorders arising from inflammations, whereof the chief are old gonorrhoes, consumptions, and the rheumatism without a fever. See the preceding articles and references.

All these diseases are the consequences of catching colds, and are prevented by the same means as colds. See COLD.

Bleeding is the most indispensable remedy in the cure of all inflammatory diseases, and therefore to the delaying this too long, or not repeating it, it is owing, that colds end in dangerous fevers, rheumatisms, or consumptions. See BLEEDING.

In all inflammatory disorders, the principal intention of cure is to diminish the force of the blood, to thin it, and to relax the fibres; on which account, bleeding, attenuants, and diaphoretics, are the chief remedies. Physicians have generally supposed, that the increased action of the blood-vessels in inflammatory diseases increases the tendency of coagulation in the crassamentum. But Mr. Newton has advanced a new doctrine, which has also been adopted by Dr. George Fordyce, in his Elements of the Practice of Physic, viz. that inflammation instead of increasing, lessens the disposition of the blood to coagulate, and instead of thickening, thins it, at least its coagulable part; the surface of blood which is about to form a crust or rind, remaining much longer fluid than that of blood in different circumstances: and he supposes that what floats on the surface of such blood is coagulable serum, augmented by the increased action of the blood-vessels. Phil. Trans. vol. 1. p. 255. An early sweet rind also to prevent an inflammatory fever, for which purpose, the diaphoretic draught of the Edinburgh dispensatory is recommended; or, instead of it, a spoonful of the plain spiritus Mindereri may be given every two hours, till a sweat breaks out, or two spoonfuls of the salt of hartshorn, saturated with about three spoonfuls of common vinegar, may be given in one draught at bed-time. Pringle, Observ. on the Diseases of the Army, p. 77, 127, &c.

INFLAMMATORY fevers. See ardent or inflammatory Fevers.

INFLATION, formed from *in*, and *status*; of *fit*, I blow; blowing up, the act of stretching or filling any fluid, or distensible body, with a flatulent or winy substance.

INFLECTION, called also *diffraction*, and *deflection*, in Optics, is a property of light, by reason of which, when it comes within a certain distance of any body, it will either be bent from it, or towards it; which is a kind of imperfect reflection or refraction.

This property was first taken notice of by Dr. Hooke; who shews that it differs both from reflection and refraction, and seems to depend on the unequal density of the contiguous parts of the ray, whereby the light is diffused from the place of condensation, and rarefied or gradually diverged into a quadrant: and this deflection, he says, is made towards the superficies of the opaque body perpendicularly. Some writers ascribe the first discovery of it to Grimaldi, the Jesuit. He first published an account of it, in his treatise De Lumine, Coloribus, & Iris, printed in 1666; not did any other person lay claim to the discovery, except Dr. Hooke, who communicated his observations on this subject to the Royal Society, in 1672. It appears, however, that Dr. Hooke had not heard of the discovery of Grimaldi; for he speaks of his own, as a discovery of a new property of light, not mentioned by any optical writer before him. See DIFFRACTION.

Sir Isaac Newton discovered also, by plain experiment, this inflection of the rays of light; and M. de la Hire assures us he found, that the beams of the stars being observed, in a deep valley, to pass near the brow of a hill, are always more refracted than if there were no such hill, or the observations were made on the top thereof; as if the rays of light were bent down into a curve, by passing near the surface of the mountain.

Sir Isaac Newton, in his Optics, makes several experiments and observations on the inflection of the rays of light; which see under LIGHT, and RAY.

M. de la Hire observed, that when we look at a candle, or any luminous body, with our eyes nearly shut, rays of light are extended from it, in several directions, to a considerable distance, like the tails of comets. The true occasion of this phenomenon, which has excited the curiosity of Des Cartes, Rohault, and others, seems to be, that the light passing among the eye-lashes, in this situation of the eye, is inflected by its near approach to them, and therefore enters the eye in a great variety of directions.

INFLECTION, in Grammar, the variation of nouns and verbs, in their several cases, tenses, and declensions. Inflection is a general name, under which are comprehended both CONJUGATION and DECLENSION.

INTERSECTION, point of, of a curve, in Geometry, is a point or place where the curve begins to bend, or turn in a contrary way.

If a curve line, as A P K (Tab. III. Geometry, fig. 12), be partly convex, and partly convex towards any right line, as A B, or towards a fixed point, the point P, which divides the concave from the convex part, and consequently is at the beginning of the one and end of the other, is called the point of inflection, as long as the curve, being continued beyond P, keeps its course the same: when it returns back again towards that part or side, from whence it took its original, it is called the point of retrogression. See the article RETROGRESSION.

To conceive this, it is to be considered, that any quantity which goes on continually increasing or decreasing, cannot change from a positive to a negative expression, or from a negative to a positive one, without first becoming equal to an infinite, or nothing. It becomes equal to nothing, if it continually decreases; and equal to an infinite, if it continually increases.

Now, if through the point P be drawn the ordinate T F, and the tangent P L, and from any point, as M, on the same side of A P, be drawn the ordinate M P, and the tangent M T; then in curves which have a point of inflection, the abscissas A P continually increase, and the part A T of the diameter, intercepted between the vertex of the diameter and the tangent M T, increases also, till the point P fall into E; after which it again begins to diminish: whence the line A T must become a maximum A L, when the point P falls into the point L. In those curves which have a point of retrogression, the part A T increases continually, and the abscissas increase, till the point T fall into L; after which it again diminishes: whence A P must become a maximum, when the point T falls into L.

If $AE = x$, $EF = y$, then will $AL = \frac{x^2}{2y} - x$ (see TANGENT) whose FLUXION, which is $\frac{x^2 - 2xy}{2y^2} - x$

$\frac{x^2 - 2xy - 2x^2}{2y^2} = -\frac{x^2 + 2xy}{2y^2}$ supposing a constant, being divided by x , the fluxion of A L must become nothing; i. e.

i. e. $\frac{-y}{x} = 0$: so that multiplying by y^2 , and dividing by $-y$, $y = 0$: which is a general form for finding F , the point of inflexion, or retrogression, in those curves whose ordinates are parallel to one another. For the nature of the curve APK being given, put the equation of the curve into fluxions; from which, or from other properties of the curve, find the value of x or y , and put this x or y and its value into fluxions, making both x and $y = 0$: then by expanding the rest of the fluxional quantities, we shall determine the value of x , i. e. AE or y , i. e. EF , at the point of inflexion sought.

Ex. gr. To find the point of inflexion B in the curve ABY (for. 54.) whose equation (putting the absciss $AC = x$, ordinate $CB = y$, and the perpendicular $AE = a$) is $a^2 = a^2y + x^2y$. From the fluxion of this equation, viz. $2ax = a^2\dot{y} + 2xy\dot{x} + x^2\dot{y}$ we deduce $\dot{y} = \frac{2ax - 2xy\dot{x}}{a^2 + x^2}$

i. e. by substituting for y its value $\frac{a^2}{a^2 + x^2}$, $\dot{y} = \frac{2ax - 2x \cdot \frac{a^2}{a^2 + x^2} \dot{x}}{a^2 + x^2}$, and the fluxion of this equation, making both x and $y = 0$, is $0 = \frac{2a^2\dot{x} \cdot a^2 + x^2 \cdot a^2 - 4a^2x \cdot x + 4x^2 \cdot x \cdot 2a^2\dot{x}}{a^2 + x^2}$ which multiplied by $a^2 + x^2$ and divided by $2a^2\dot{x}$, gives $0 = a^2 + x^2 - 4x^2 - 4x^2$; therefore, $4x^2 + 4x^2 = a^2 + x^2$; which equation divided by $x^2 + a^2$ makes $4x^2 = a^2 + x^2$; therefore $3x^2 = a^2$, and $x = a\sqrt{\frac{1}{3}}$, and if this value be substituted for it in the given equation of the curve, we shall have y , or the ordinate at

the point of inflexion $= \frac{a^2}{a^2 + a^2} = \frac{a^2}{2a^2} = \frac{a^2}{2}$

$\frac{3a^2 + a^2}{3} = \frac{4a^2}{3}$. Let AC be equal to $\frac{1}{2}AE$, and with the radius $\frac{1}{2}AE$, describe the arc EC ; then will C be the point from which the ordinate to the point of inflexion must be drawn: for $EC = \frac{1}{2}a$; and $CP = EA^2 = AC^2$, i. e. $\frac{1}{4}a^2 = \frac{1}{4}a^2 = \frac{1}{4}a^2 = AC^2 = a^2$; or $a = a\sqrt{\frac{1}{3}}$.

In order to know whether any curve be concave or convex towards a point aligned in the axis, find the value of y at that point; then if this value be positive, the curve will be convex towards the axis, and if it be negative, it will be concave. For other methods of determining the point of inflexion in different curves, see Simpson's Fluxions, vol. i. p. 65. Rowe's Introduction, &c. part i. chap. 5. The rule for determining the points of contrary flexure and retrogression of curves, which supposes the second fluxion of the ordinate to be nothing or infinite, i. e. $y = 0$, or ∞ , is liable to several exceptions, as is shown very fully and clearly by Mr. Maclaurin, in his Treatise of Fluxions, book i. chap. 9. book ii. chap. 5. art. 866 and 867.

The ordinate y passes through a point of contrary flexure, when the curve being continued on both sides of the ordinate, y is a maximum, or minimum. But this does not always happen when $y = 0$, or ∞ . Mr. Maclaurin observes, in general, that if y , $\dot{y}$, &c. vanish, the number of these fluxions being odd, and the fluxion of the next order to them having a real and finite value; then y passes through a point of contrary flexure; but if the number of these fluxions that vanish be even, it cannot be said to pass through such a point; unless it should be allowed that a double infinitely small flexure can be formed at one point.

The curve being supposed to be continued from the ordinate y , on both sides, if y be infinite, the extremity of the ordinate therefore is not always a point of contrary flexure, as y is not always, in this case, a maximum, or minimum; and the curve may have its concavity turned the same way on both sides of the ordinate. But these cases may be distinguished by comparing the signs of y on the different sides of the ordinate; for when these signs are different, the extremity of y meeting the curve is a point of contrary flexure.

The suppositions $y = 0$, or ∞ , and of $y = 0$, or ∞ , serve to direct us where we are to search for the maxima and minima, and for points of contrary flexure; but we are not always sure of finding them. For though an ordinate or fluxion that is positive, never becomes negative at once, but by increasing and decreasing gradually, yet after it has decreased till it vanish, it may thereafter increase, continuing still positive; or after increasing till it becomes infinite, it may thereafter decrease without changing its sign.

INFLUENCE, a quality supposed to flow from the bodies Vol. II. N° 135.

of the stars, either with their heat, or light, to which astrologers vainly attribute all the events which happen on the earth.

Alechemists, also, who to this strive the philosophers shun, tell us, that every thing in nature is produced by the influence of the stars, which in their passage through the atmosphere, imbue many of its moist parts, the gruffest whereof they deposit in the sands and earths, where they fall; that these, filtrating through the pores of the earth, descend even to the centre, whence they are driven by the central fire back again to the surface; and in their ascent by a natural kind of sublimation, as they find earths duly disposed, they form natural bodies, as metals, minerals and vegetables, &c. Thus, it is pretended, that chemistry, consisting of an artificial imitation of these natural operations, and in applying active principles to passive principles, can form natural bodies, make gold, &c. See TRANSFORMATION, and PHILOSOPHERS STONE.

INFLUENT, a term used where a liquor or juice, by the contrivance of nature, and the laws of circulation, falls into any current or receptacle.

Thus with respect to the common receptacle, the chyle is its influent juice; and so is the bile to the gall-bladder, the venal blood to the heart in its diastole; and the like.

INFLUENT fever is sometimes used for a *tertiana* fever. In this the warm regimen is thought useful by some, as low cooling drinks are in the effluat or inflammatory fever.

INFORCED. } See { REINFORCED.
INFORCEMENT. } See { REINFORCEMENT.

IN FORMA PAUPERIS, in Law. See Forma Pauperis.

INFORMATION, in Law, for the king, is much the same with what is called DECLARATION for a common person: it is not always done directly by the king, or his attorney, or the clerk of the crown-office, but sometimes by another, who acts as well for the king as himself, on a breach of some penal law or statute, wherein a penalty is given, one part to the use of the king, and another to the use of the informer. And it differs from an indictment, which is found by the oath of twelve men; and it only the allegation of the officer who exhibits it. The latter sort of information, which are partly at the suit of the king, and partly at that of a subject, is a species of *qui tam* actions, so called, because they are brought by a person, *qui tam pro domino regi, &c. quam pro seipso in hac parte sequitur*, and carried on by a criminal instead of a civil process. By 31 Eliz. c. 5. no prosecution of this kind can be brought by any common informer, after one year is expired since the commission of the offence; nor out of the county where the offence was committed; nor on behalf of the crown after the lapse of two years longer; nor, where the forfeiture is originally given to the king alone, can such prosecution be had after the expiration of two years from the commission of the offence. It is also enacted by 18 Eliz. c. 5. that if any person, informing under pretence of any penal law, makes any composition without leave of the court, or takes any money or promise from the defendant to excuse him, he shall forfeit ten pounds, stand two hours on the pillory, and be for ever disabled to sue on any popular or penal statute. And by the same statute, if a person exhibits his information only for vexation, the defendant may bring information against the informer.

Informations that are exhibited in the name of the king alone are of two kinds; those which are truly and properly his own suits, and filed *ex officio* by his own immediate officer, the attorney-general; and those, in which, though the king is the nominal prosecutor, yet it is at the relation of some private person or common informer; and they are filed by the king's coroner and attorney in the court of king's bench, usually called the master of the crown-office, who, for this purpose, is the standing officer of the public. The objects of the king's own prosecutions, filed *ex officio* by his own attorney-general, are properly such enormous misdemeanors as particularly tend to disturb or endanger his government, or to molest or affront him in the regular discharge of his royal functions. The objects of the other species of information are any gross and notorious misdemeanors, riots, batteries, libels, and other immoralities of an atrocious kind. And when an information is filed, in either of these ways, it must be tried by a petit jury of the county where the offence arises; after which, if the defendant be found guilty, he must resort to the court for his punishment. These informations of every kind are confined by the constitutional law to mere misdemeanors only, without extending to any capital offence. The oppressive use of information by the court of Star-chamber, &c. in the times preceding the Revolution, occasioned a struggle soon after the accession of king William, to cure

enure a declaration of their illegality by the judgment of the court of king's bench. But Sir John Holt, who then presided there, and all the judges, were clearly of opinion, that this proceeding was grounded on the common law, and could not then be impeached. However, in a few years afterwards, it was enacted by 4 and 5 W. and M. c. 18, that the clerk of the crown should not file any information without express direction from the court of king's bench; and that every prosecutor, permitted to promote such information, shall give security by a recognizance of twenty pounds, to prosecute the same with effect; and to pay costs to the defendant, in case of his acquittal, unless the judge, who tries the information, shall certify there was a reasonable cause for filing it; and at all events, to pay costs, unless the information shall be tried within a year after issue joined. But there is a proviso in this act, that it shall not extend to any other informations than those which are exhibited by the master of the crown office; and, consequently, informations at the king's own suit, filed by his attorney-general, are not yet restrained thereby.

There is one species of informations still further regulated by 9 Ann. c. 20. viz. those in the nature of a writ of *quo warrantum*, which is a remedy given to the crown against such as had usurped or intruded into any office or franchise. The modern information tends to the same purpose as the ancient writ, being generally made use of to try the civil rights of such franchises, though it is commenced in the same manner as other informations are, by leave of the court or at the will of the attorney-general, being properly a criminal prosecution, in order to sue the defendant for his usurpation, as well as to oust him from his office; yet usually considered at present as merely a civil proceeding.

An information on behalf of the crown, filed in the exchequer by the king's attorney-general, is a method of suit for recovering money or other chattels, or for obtaining satisfaction in damages for any personal wrong committed in the lands or possessions of the crown. The most usual informations are those of *trespass* and *deceit*; the former being for any trespass committed on the lands of the crown, as by entering thereon without title, holding over after a lease is determined, taking the profits, cutting down timber, or the like; and the latter upon any contract for monies due to the king, or for any forfeiture due to the crown upon the breach of a penal statute. There is also an information *in rem*, usually filed in the exchequer, where any goods are supposed to become the property of the crown, if no man appears to claim them, or to dispute the title of the king. There is also another information filed *ex officio* by the attorney-general in the court of chancery, at the relation of some informant, called the relator, for the proper establishment of charities, of which the king has the general superintendence. Blackst. Com. b. iii. p. 261. 427. b. iv. p. 435. 433. &c.

INFORMATUS *sum*, or *Notum* **INFORMATUS**, a formal answer made of course by an attorney, who is commanded by the court to say any thing he thinks good in behalf of his client; who having nothing material to urge, makes answer, he is not informed on which judgment passes for the other party.

INFORMER, *informer*, in *Law*, a person that informs against, or prosecutes in any of the king's courts those that offend against any law or penal statute. See **INFORMATION**.

INFORMIS, *informed*, that which has not the form or perfection it should have.

INFORMES *Stellæ*, in *Astronomy*, are such stars as have not yet been reduced to any constellation; otherwise called *sterræ*.

Of this kind there was a great number left by the ancient astronomers, but Hevelius and some others of the moderns, have provided for the greater part of them by making new constellations.

INFRACTION, formed of *in*, and the supine of *frangere*, *Infra*, a rupture, or violation of a treaty, law, ordinance, or the like.

INFRAAPSARIUM, the name of a sect of Predisinarians, who maintain, that God has created a certain number of men only to be damned, without allowing them the means necessary to save themselves, if they would; and they are thus called, because they hold that God's decrees were formed *infra lœsum*, after his knowledge of the fall, and in consequence thereof; in contradistinction to the **SUPRAAPSARIANS**.

INFRASPINATUS, called also *Infraclavicularis*, a muscle which arises from the inferior parts of the back, spine, and under-ribs of the scapula, and which, filling the lower intercapulum, passes on between the spine and lesser minor, in a triangular form; and, growing tendinous at the cone, is inserted into the head of the humerus,

and draws directly backwards.—See *Tab. Anat. (Myl.)* fig. 7. n. 33.

INFUNDIBULANS, a term used by some of the writers in medicine, to express the cereate or corymb.

INFULA, a name anciently given to one of the pontifical ornaments worn on the head. Pelsus tells us, that the *infula* were filaments or fringes of wool, covering that part of the head where the hair grows as far as the temples, whence, on each side, hung down two strings called *vitæ*, for binding it, wherewith the ancients used to adorn their priests, their victims, and even their temples. The *infula* was the same thing to priests that the diadem was to kings; viz. the badge of their dignity and authority. The difference in shape between the diadem and the *infula* consisted in this, that the diadem was flat and broad, and the *infula* was rounded and twilled.

INFUNDIBULIFORM *Flowers*. See **FLOWERS**.

INFUNDIBULUM, a Latin word, signifying a funnel; whence divers parts in the human body, having a resemblance thereto in shape, are called by the same name.

Such as, gr. art. the *infundibulum cerebri*, and *infundibulum rectoris*. See **BRAIN**, and **KIDNEYS**.—See also *Tab. Anat. (Optic.)* fig. 5. lit. c.

Hence also certain parts of plants are called *infundibuliformes*.

The word *infundibulum* is also used by the metallurgic writers to signify a vessel of a conic shape, used to pour a melted metal out of the crucible into.

INFUSION, in *Pharmacy*, an operation whereby the virtues of plants, roots, and the like, are drawn out, by letting them steep in some convenient fluid menstruum, without boiling them therein; since boiling is found to dissipate the finer parts of many bitter and aromatic substances, without carefully extracting their medicinal principles.

Infusum is used in bodies of a lax texture, whose parts are so light as not to admit of a greater motion without hazard of flying away in vapour.

Its chief use is to communicate the virtues of bodies to liquors, either in order to regulate their force, or correct their ill qualities.

Some *infusum* are made in common water, others in wine, vinegar, milk, spirit of wine, &c.

The bitter *infusum* is prepared by cutting the tops of the lesser centaury and camomile flowers, of each half an ounce, and the yellow rind of lemon and orange peel, of each two drams, in small pieces, and infusing them in a quart of boiling water. A tea-cupful of this *infusum* may be taken twice or thrice a day for indigestion, flatulencies of the stomach, or want of appetite.

Infusum of the bark, is made by infusing an ounce of powder in a pint of boiling water, with the addition of four or five table-spoonfuls of brandy, for two or three days. In disorders which require the bark, a tea-cupful of this may be taken two or three times a day.

Infusum of carduus, is made by infusing an ounce of the dried leaves of carduus benedictus in a pint of common water, for six hours, without heat, and then filtering the liquor through paper. This *infusum* which may be flavoured at pleasure, with cinnamon, or other aromatics, may be beneficially used in weaknesses of the stomach, where the common bitters do not agree.

Infusum of linseed, is prepared by infusing two spoonfuls of linseed, and half an ounce of liquorice-root sliced in three pints of boiling water by the fire for some hours, and then straining off the liquor. The pectoral *infusum* is made by adding to these ingredients an ounce of the leaves of colts-foot. These emollient liquors may be taken in diffusibility of making water, and in coughs, and other complaints of the breast.

Infusum of roses, is made by infusing half an ounce of red roses, dried, for four hours in a quart of boiling water, in an unglazed earthen vessel; afterwards pouring in half a dram of the vitriolic acid, called oil of vitriol, straining the liquor, and adding to it an ounce of loaf sugar. A tea-cupful of thisstringent *infusum* may be taken every three or four hours in an excessive flow of the menes, vomiting of blood, and other hemorrhages. It will likewise serve as a very good gargle.

Infusum of tamarinds and fennel, is prepared by infusing for four or five hours one ounce of tamarinds, and fennel and crystals of tartar, of each two drams, in a pint of boiling water; straining the liquor, and adding to it an ounce or two of the aromatic tincture. Persons who are easily purged, may leave out either the tamarinds or the crystals of tartar. A tea-cupful of this agreeable cooling purge may be taken every half hour till it operates.

Spanish *infusum* is made by infusing an ounce of Spanish juice cut into small pieces, and three drams of tals of tartar in a quart of boiling water for a night; and adding to the strained liquor an ounce and a half of the syrup

lyrup of poppies. In recent colds, coughs, and obstructions of the breast, a tea-cupful of this *infusion* may be taken with advantage three or four times a day. See *Liquorice*.

An *infusion* for the palsy may be made by infusing horse-radish-root sliced, mustard-seed bruised, of each four ounces; and one ounce of the outer rind of orange-peel, in two quarts of boiling water, in a close vessel, for twenty-four hours. A tea-cupful of this warm stimulating medicine may be taken three or four times a day, in paralytic complaints. It excites the action of the solids, proves diuretic, and, with warmth, promotes perspiration. If two or three ounces of the dried leaves of marsh-mallows be used instead of the mustard, we shall have the anti-scorbutic *infusion*. *Buchan's Dom. Med. Appendix.*

INFUSION is also used to signify the action of conveying liquor into the body by the veins. See *INJECTION*. Some physicians have found out a new method of purging, by *infusing* a cathartic into the veins, which operates pretty much after the manner of a clyster.

INGA, in *Botany*. Its characters are these: the flower has a permanent empilement divided into five parts at the top; it has one petal, is funnel-shaped, and cut into five fringed segments at the brim, out of which arise a great number of filamina, which are three times the length of the tube; at the bottom of the tube is situated an oblong germen, which becomes a fleshy pod, including several irregular seeds. There are two species, natives of the West Indies. *Miller*.

Linnaeus has joined this genus to the *MIMOSA*.

INGANNO, in the *Italian Style*, is used, when the composer, after having done every thing proper for making a close or cadence, instead of so doing places a mark of fineness in the place of the final note. This word is Italian signifying *deceit*.

INGEMINATED FLOWERS, are those where one flower stands on, or naturally grows out of, another; called also *proliferous flowers*.

INGENDING. See *ENGINEERING*.

INGENITE, *Inertia*, signifies any diftate, or habit, which comes into the world with a person: nearly the same with *HEREDITARY*.

INGENUITAS *regni*, anciently signified the freeholders and commonalty of the kingdom: the title was also sometimes given to the barons and lords of the king's council.

INGENUOUS, *Ingenum*, among the Romans, a title applicable to a person born FREE, or of free parents. *Indore* says, they are called *ingeni*, *qui libertatem habent in genere non in factis*; those who are born free, not those who acquire their freedom.

A person was accounted *ingenus*, if only the mother were free, and the father a slave.

These could give their votes, and enjoy offices from which the *liberti*, or freedmen, &c. were debarred.

INGENUOUS is sometimes also used to signify a NATIVE of a country in contradistinction to a foreigner.

INGESTA is used by some authors to express all sorts of aliment taken into the body.

ENGINEER, or **ENGINEER**. See *ENGINEER*.

INGLUVIES. See *CRAW*.

INGOT, a mass, or lump of GOLD or SILVER, from the mines, melted down and cast in a sort of mould, but not coined, or wrought.

The word seems formed from the French *ingus*, which signifies the same.

INGOT is also a name given to the moulds or cavities, wherein they cast melted metals, or regulus of semimetals.

INGRAFTING, or **ENGRAFTING**. See *ENGRAFTING*.

INGRAILED. See *ENGRAILED*.

INGRAVING, or **ENGRAVING**. See *ENGRAVING*.

INGREDIENTS, all the simples which go into the composition of any medicine, element, sauce, or the like.

INGRESS, in *Astronomy*, the sun's entering the first scruple of one of the four cardinal signs, especially Aries.

INGRESS, **EGRESS**, and **REGRESS**, in *Law*, are words in cases of land, signifying a free entry into, a going out of, and returning from some part of the premises leased to another: as to get in a crop of corn, &c. after the term expired.

INGRESSU, in *Law*, a writ of ENTRY, whereby a person seeks entry into lands or tenements. It lies in various cases, and has various forms. It is also called *FRACITE quod reddit*.

INGROSSATOR *magni estuli*, is the same as *CLERK* of the pipe.

INGROSSER, or **ENGROSSER**, in *Common Law*, is one who buys up corn growing, or any provisions by wholesale, before the market, to sell again. See *FORESTALLING*.

Italo signifies a clerk, who writes records, or instruments of law, on skins of parchment. See *ENGROSSING*.

INGROSSING of a fine, is the making the indentures by the CHIROGRAPHER, for delivery of them to the party to whom the fine is levied.

INGUEN, that part of the body, reaching from the head of the thigh to above the secret parts; commonly also called the groin, and by anatomists pubes.

The word is pure Latin, and is derived, according to *fove*, from *inguen*, *inguent*, because these parts are frequently ained. Others derive it from *ang*, because pains happen frequently there; and others again from *ingens*, because the genital parts are here.

INGUINAL glands. See *GLANDS*.

INGUINAL ligament. This, which has been also called from its discoverer *ligamentum FALLORII*, is an aponeurotic, or ligamentary band, fastened by one end to the anterior and superior part of the os ilium, and by the other to the spine of the os pubis. The middle portion of it is very narrow, but it expands considerably towards both its extremities. It is closely joined to the muscles of the abdomen, and to the aponeurotic fascia of the thigh, but seems to be often wanting.

INGUINALIS, an appellation given to any subdivision made of the *inguen*; or any thing therein contained, or applied thereto by way of medicine, or the like.

INGUINALIS, hernia. See *HERNIA* and *BURDONCELLE*.

INHARMONICAL relation, in *Music*. See *RELATION inharmonic*.

INHERENCE, in *Philosophy*, is applied to the juncture or connexion of an accident with its substance.

Thus quantity has a necessary *inherence* in a natural body.

INHERITANCE, *Hereditas*, a property in lands and tenements, to a man and his heirs.

Inheritance is not only understood where a man hath inheritance of lands and tenements by descent or bequest; but every fee-simple or fee-tail, that a man hath by his purchase, may be said to be an inheritance, for that his heirs may inherit it after him. The inheritances mentioned in our law are either corporeal or incorporeal; the corporeal relate to houses, lands, &c. that may be touched or handled; and the incorporeal are rights issuing out of, annexed to, or exercised with corporeal inheritances, as advowsons, tithes, annuities, offices, commons, franchises, &c. There is likewise another inheritance denominated *feudal*, that is, where two or more hold lands fevally; as when two persons hold to them and the heirs of their two bodies, in which case these two have joint estate during their lives, but their heirs have several inheritances. Goods and chattels cannot be turned into an inheritance. For the rules of inheritance, see *DESCENT collateral*.

INHIBITION, a writ to inhibit or forbid a judge from farther proceeding in a cause depending before him.

Sometimes *prohibition* and *inhibition* are put together, as of the same import; but *inhibition* is most commonly a writ issuing out of a higher court-christian to a lower; and *prohibition* out of the king's court to an inferior court.

INHOC, or **INMOKE**, in our *Old Writers*, is used for any corner or part of a common field ploughed up and sowed with oats, &c. and sometimes fenced in with a dry hedge, in that year wherein the rest of the same field lies fallow and common. It is called in the North of England an *intake*, and in Oxfordshire a *hitchin*. And no such *inhoc* is now made without the joint consent of all the commoners, who in most places have their share by lot in the benefit of it, except in some manors where the lord has a special privilege of so doing. Kennet's Paroch. Antiq. 297, &c. and his Glossary.

The word is Saxon, compounded of *in*, *within*, and *hok*, a corner.

INHUMATION. See *BURIAL*, and *INTERMENT*.

INIMUTATION, in *Chemistry*, a method of digesting substances together, by burying the vessel, in which they are put, in horse-dung, or in a dry sandy earth exposed to the sun. See *DIGESTION*.

INJECTION, in *Pharmacy*, any liquid medicine made to be injected or thrown into the body, or any of its parts, by a syringe, clyster-pipe, or other instrument.

INJECTION, or **INJECTION**, in *Surgery*, the throwing in some liquor or medicine into a vein opened by incision. This practice, and that of *TRANSFUSION*, or the conveying the arterial blood of one man, or other animal, into another, were once greatly practised, but are now laid aside.

The method of *injection* is this; a vein is to be opened in the arm with a lancet as in bleeding, and the small pipe of a syringe being introduced at the orifice, the liquor intended to be mixed with the blood, and contained for that purpose in the body of the syringe, is to be forcibly injected, or thrown into the vein upwards, or toward the heart; which done, the orifice is to be secured with compresses and bandage, as in bleeding.

Whether

Whether this practice of injecting proper medicines into the blood may not be found of use in apoplexies, quinseys, hydrophobias, &c. is worthy to be tried by repeated experiments. The method of *injecting* liquors into the blood of living animals, is said to be the invention of Sir Christopher Wren. His method was by making ligatures on the veins, and opening them on the side of the ligature towards the heart; then putting into them small syringes or quills fastened to bladders, in the manner of clyster-pipes, containing the matter to be *injected*. Mr. Boyle soon made the experiment upon dogs, with infusions of opium and crocus metallorum; all which he circumstantially described, in his *Usefulness of Experimental Philosophy*, part ii. c. 2. Phil. Trans. N^o 7, p. 128.

The ingenious Dr. Hales made a variety of experiments of this kind on different animals. See his *Statical Essays*, vol. ii. passim.

Many disorders of particular parts are no way curable, unless the parts affected are *injected* with a proper liquor, by means of a syringe and proper tube. The method of performing this is too obvious to need any directions; but these general cautions are necessary in regard to it, that the syringe or tube be applied tenderly and carefully to the parts, especially in very sensible or nervous parts, to avoid giving the patient any pain; and that the liquor to be *injected* be neither too hot nor too cold.

In ulcerations and inflammations of the urethra, testis, and fauce, *injections* are generally useful; but care must be taken to press down the tongue with a spatula, or with the flat end of a spoon, and having introduced the syringe two or three fingers breadth into the mouth, the *injection* is to be carefully and gently thrown in at several times. In gonorrhoeas, *injections* are often necessary, to allay the heat and ferocity of the urethra; and to wash out the matter. The safest and best *injection* on this occasion, are warm milk, and barley-water, sweetened with sugar, honey, oil of sweet of marshmallows; and towards the end a little saccharum saturni, dissolved in plantane water. Heister's Surgery, p. 317.

INJECTION, anatomical, is used for the operation of filling the vessels with coloured wax, or any other proper matter, to show their figures and ramifications. These are coloured, in order to make the parts more conspicuous. Mr. Moore uses red and green chiefly. For the red, vermilion finely levigated must be got. For the green, distilled verdigris is best; because its colour is brighter than that of the common ferr, and it never runs into knots, and also diffuses in oily liquors.

To make the face *injection*, pour a pint of the oil of turpentine on three ounces of vermilion, or verdigris; stir them well with a wooden spatula till they be thoroughly mixed, and then strain all through a fine linen rag.

The coarser *injection* is thus made: take tallow 1 lb; white wax $\frac{3}{4}$ v; oil of olives $\frac{3}{4}$ iii; melt them over a gentle fire; then add of Venice turpentine $\frac{3}{4}$ ij. When this is dissolved, sprinkle in of vermilion or verdigris $\frac{3}{4}$ iii, then pass all through a warm linen cloth. When you design to make it run far in the vessels, add some oil of turpentine immediately before you use it.

As to the practice of *injections*, we refer to the Medic. Ess. Edinb. vol. i. art. 9.

INIMBOY, in *Botany*, a name by which some authors have called the acacia gloriosa, the tree which produces the bonduch or bezoar nuts.

INITIALIA, a name anciently given to the mysteries of Ceres. See CEREBALIA.

INITIANS paulum, See PUNCTUM.

INITIATED, a term properly used in speaking of the religion of the ancient heathens; where it signifies being admitted to the participation of the sacred mysteries.

The word comes from the Latin *initiare*, of *initiare*, *initiare*, which properly signifies to begin sacrificing, or to receive or admit a person to the beginning of the mysteries, or of ceremonies of less importance.

The ancients never discovered the deeper mysteries of their religion, nor even permitted some of their temples to be open to any but those who had been initiated. See MYSTERY.

INJUNCTION, in *Law*, a writ generally grounded upon an interlocutory order or decree out of the court of chancery or exchequer, sometimes to give possession to the plaintiff, for want of the defendant's appearance; sometimes to the king's ordinary court, and sometimes to the court-chancellor, to stop proceedings in a cause, upon suggestion made, that the rigour of the law, if it take place, is against equity and conscience in that case, that the complainant is not able to make his defence in these courts, for want of witnesses, &c. or that they act erroneously, denying him some just advantage. The writ of *injunctio*, is directed not only to the party himself, but

to all and singular his counsellors, attorneys, and solicitors, and if any attorney, after having been served with an *injunctio*, proceeds afterward contrary to it, the court of chancery will commit the attorney to the Fleet for contempt. But if an *injunctio* be granted by the court of chancery in a criminal matter, the court of king's bench may break it, and protect any that proceed in contempt of it.

INJURY, *injuria*, in a general sense, signifies any thing contrary to justice and equity; that is, any wrong or damage done to a man's person, reputation, or goods. The word is derived from the Latin preposition *in*, which here has a negative power; and *jus*, *ius*, right: *injuria* *dictur* *ammi* *quod* *non* *jure* *fit*. The ancients made a god-dels of *injuria*, and called her Atre. Homer makes her the daughter of Jupiter, and says, she did mischief to every body, even to her father; that she was very nimble and tender-footed, and walked altogether on men's heads without ever touching the ground.

Civilians define *injuria* a private offence, committed designedly, and with an evil intention to any man's prejudice, with regard to his person or his property. All civil *injuria* are of two kinds; the one without force or violence, as slander, or breach of contract; the other joined with force and violence, as batteries, and false imprisonment. The author of the Rhetorics to Herennius says, *Injuria est* *quæ* *aut* *passiones*, *aut* *veritate*, *aut* *injuriis*, *corpore*, *animi*, *aut* *alioquin* *abruptis* *violantur*.

By the Roman law, the action for an *injuria* was annual; that is, no reparation could be required after the expiration of a year. By the law of the Twelve Tables, where the *injuria* was the breaking of a limb, the injured person might demand talionem; that is, that he might break the same limb of the criminal.

For the breaking of a bone there were also considerable pecuniary punishments assigned: for other *injuria* only twenty asses were decreed, which the poverty of those times thought a sufficient penalty; but the praetors afterwards finding this too slender a satisfaction, in lieu thereof appointed the injured person to set a rate on the *injuria*, which they afterwards increased or lessened as they thought good.

Some of our lawyers make a distinction between a *damage* and an *injury*; and indeed there are many acts which may be done to the prejudice of a third person, which may be properly said to be *damnum sine injuria*.

INK, a liquor wherewith to write on paper or parchment.

INK, printing. See PRINTING. **INK, writing**, is commonly made of copperas, gum arabic, and gum arabic; but other astringent plants may be used, as the fume purple; such as oak-bark, red roses, log-wood, or sumach. Mr. Boyle seems to doubt whether all astringent vegetables will do the same.

Many are the propositions, and methods of compounding the materials for making of writing ink. The author of the Chemical Dictionary gives the following receipt for making good ink. In four French pints of common water or beer, let a pound of bruised galls be infused twenty-four hours without boiling; to this add six ounces of gum arabic; and when the gum is dissolved, six ounces of green vitriol, which will soon give it the black colour; the liquor is then to be strained through a hair sieve.

The following method has been recommended by experience, and is easily and speedily practised. To a gallon of boiling water, put six ounces of blue galls, grossly pounded, and three ounces of copperas; stir the mixture well together, and then add six ounces of gum arabic pounded. After stirring the whole thoroughly, leave it to settle, and the next day strain it off from the dregs for use. See *INK* *juice* *palestini*.

The following composition will make a very good black writing ink. Take a gallon of soft water, and boil in it a pound of chips of logwood for about half an hour; pour the decoction boiling hot on a pound of the best Aleppo galls powdered, and two ounces of pomegranate peels, put into a proper vessel. After having stirred them well together with a wooden spatula, place them in the sun-shine in summer, or within the warmth of any fire in winter, for three or four days, stirring the mixture occasionally; then add half a pound of green vitriol powdered, and let the mixture remain four or five days more, occasionally stirring it; and then add four ounces of gum arabic dissolved in a quart of boiling water; and when the ink has settled, strain it off through a coarse linen cloth, and keep it well stop for use.

As the duration of records and other valuable writings depends much on the goodness of the ink employed, Mr. Lewis has thought this subject worthy of his attention. The chief imperfection of common ink is, that the more it is in time, and at last the writing becomes invisible.

From experiments made by that author, he infers, that the decay of *inks* is chiefly owing to a deficiency of galls; that the galls are the most perishable ingredient, the quantity of these, which gives the greatest blackness at first (which is about equal parts with the vitriol) being insufficient to maintain the colour; that for a durable *ink*, the quantity of galls cannot be much less than three times that of the vitriol; that it cannot be much greater without lessening the blackness of the *ink*; that by diminishing the quantity of water, the *ink* was rendered blacker and more durable: that distilled water, rain water, and hard spring water, had the same effects; that white wine produced a deeper black colour than water; that the colour produced by vinegar was deeper than that by wine; that proof spirit extracted only a reddish-brown tinge, and rectified spirit a paler brown; that the last mentioned tinctures sunk into, and spread upon the paper; and hence the impropriety of adding spirit of wine to *ink*, as is frequently directed, to prevent mouldiness or freezing; that other astringents, as oak-bark, bistort, floss-bark, &c. were not so efficacious as galls, nor gave so good a black, the colour produced by most of these, excepting oak-bark, being greenish; that the juice of floss did not produce a black colour with martial vitriol; but that, nevertheless, the writing made with it became black; and was found to be more durable than common *ink*; the *inks* made with saturated solutions of iron in nitrous, marine, acetic acids, in tartar, or in lemon juice, were much inferior to the *ink* made with martial vitriol; that the colour of *ink* was depraved by adding quicklime, which was done with an intention of destroying any superabundant acid which might be supposed to be the cause of the loss of the colour of the *ink*; that the best method of preventing the effects of this superabundant acid is probably by adding pieces of iron to engage it; and that this conjecture was confirmed by an instance the author had heard of, the great durability of the colour of an *ink* in which pieces of iron had been long immersed; and lastly, that a decoction of logwood used instead of water, sensibly improved both the beauty and deepness of the black, without disposing it to fade. The same author observes, that the addition of gum arabic is not only useful, by keeping the colouring matter suspended in the fluid, but also by preventing the *ink* from spreading, by which means a greater quantity of it is collected on each stroke of the pen. Sugar, which is sometimes added to *inks*, was found to be much less effectual than gums, and to have the inconvenience of preventing the drying of the *ink*. The colour of *ink* is found to be greatly injured, by keeping the *ink* in vessels made of copper, or of lead, and probably of any other metal, excepting iron, which the vitriolic acid can dissolve. The foregoing experiments point out for the best proportions of the ingredients for *ink*: one part of green vitriol, one part of powdered logwood, and three parts of powdered Aleppo, or blue galls. The best menstruum appears to be vinegar or white wine, though for common use water is sufficient. If the *ink* be required to be of a full colour, a quart, or, at most, three pints, of liquor may be allowed to three ounces of galls, and to one ounce of each of the other two ingredients. Half an ounce of gum may be added to each pint of the liquor; though the more gum we can employ, consistently with due freedom of writing, it is probable that the *ink* will be the more durable. The ingredients may be all put together at once in a convenient vessel, and well shaken four or five times each day. In ten or twelve days the *ink* will be fit for use, though it will improve by remaining longer on the ingredients; or it may be made more expeditiously, by adding the gum and vitriol to a decoction of galls and logwood in the menstruum. To the *ink*, after it has been separated from the feculencies, some coarse powder of galls, from which the fine dust has been sifted, together with one or two pieces of iron, may be added, by which its durability will be secured. It has been often remarked, says the same ingenious writer, that the *inks* used in former times were far more durable than those of later years; many modern records being more decayed than manuscripts of much greater antiquity, of which we have instances in the Letters of Camillo Paderni, published in the Philosophical Transactions for 1753 and 1754. Dr. Lewis made several experiments, in order to recover the composition of this durable *ink*. Instead of oil, which is used in the printers' *ink*, he mixed both lamp-black and ivory-black with a solution of gum arabic; this liquor wrote of a fine black colour, but when dry, it rubbed off entirely by moisture. Concluding, therefore, that the colour could not be sufficiently fixed on paper without an oily element, and as oils are made miscible with watery fluids by the intervention of gum, he mixed some of the softer printers' varnish with about half its weight of a thick mucilage of gum arabic, working them well together in a mortar, and

beat this mass with lamp-black, adding water by little and little, and continuing the rubbing, till the mixture became of a due consistence for writing. This produced characters of a full brownish black colour, which could not be discharged by rubbing, nor washed out so readily as the foregoing. Instead of the printers' varnish, or boiled oil, linseed-oil was mixed in the same manner with mucilage and lamp-black, and the mixture diluted with water; and the *ink* thus obtained was much the same as the other. To prevent the discharge by water, some of the more sinking kinds of paper, or common paper made damp as for printing, may be used, which will admit the *ink* to sink a little into its substance; and thus the characters will be as fixed as can be desired. Such Dr. Lewis found to be the ancient *inks*, that were so durable. Pliny and Vitruvius expressly mention the preparation of foot, or lamp-black, and the composition of writing-*ink* from lamp-black and gum. Dioscorides sets down the proportion of three ounces of the foot to one of gum. This mixture was formed into cakes or rolls, and dried in the sun, which were occasionally tempered with water, as the Indian *ink* is with us for painting. The ancients were sensible that these *inks* were liable to be discharged by water, and endeavoured to obviate this imperfection, according to Pliny, by using vinegar, instead of water, for tempering the mixture of lamp-black and gum, which promotes the sinking into the paper. After all, none of these *inks* can be discharged otherwise than by design; which is the case with respect to the vitriolic *ink*, and those of printed books and copper-plates.

In the course of Dr. Lewis's experiments, a farther improvement occurred to him, which was that of using the common vitriolic *ink*, instead of water, for tempering the ancient mixture of gum and lamp-black. By this method the writings will have the durability of those of former times, with all the advantage that results from the vitriolic *ink* fixing itself in the paper. Common writing *ink* may, in many cases, be improved by a small addition of the ancient composition, or of the common Indian *ink*. Lewis's Commerce of Arts, &c. p. 16.

INK powder may be prepared, by infusing a pound of galls powdered, and three ounces of pomegranate-peels, in a gallon of soft water for a week, in a gentle heat; and then straining off the fluid through a coarse linen cloth. Add to it eight ounces of vitriol dissolved in a quart of water, and let them remain for a day or two; preparing in the mean time a decoction of logwood, by boiling a pound of the chips in a gallon of water, till one third be wasted, and then straining the remaining fluid while it is hot. Mix this decoction and the solution of galls and vitriol together, and add five ounces of gum arabic, and then evaporate the mixture over a common fire to about two quarts; when the remainder must be put into a vessel proper for that purpose, and reduced to droplets in *balneo Mariae*, i. e. by hanging the vessel in boiling water. The remaining mass, after the fluid is wholly exhaled, must be well powdered; and when it is wanted for use, may be converted into *ink* by the addition of water. A portable or extemporaneous *ink* may be made without galls or vitriol, by mixing half a pound of honey and the yolk of an egg, adding two drams of gum arabic finely levigated, and thickening the whole with lamp-black to the consistence of a stiff paste; which being put to a proper quantity of water, may be used as an *ink*.

INK, Indian, or Chinese, is an admirable composition, in vain attempted to be imitated in Europe. It is not fluid, like our writing *ink*, but solid, like our mineral colours, though much lighter. They make it of all figures, but the most usual is rectangular, about a quarter of an inch thick. Some of the flicks are gilt with figures of dragons, birds, flowers, &c. In order to do this, they have little wooden moulds, so curiously wrought, that we could hardly equal them in metals.

To use this *ink*, there must be a little hollow marble, or other stone, with water in it, on which the flick of *ink* must be ground, till the water becomes of a sufficient blackness. It makes a very black thinning *ink*, and though it be apt to sink when the paper is thin, yet it never runs or spreads; so that the letters are always smooth, and evenly terminated, how big soever they be. It is of great use in designing, because it may be weakened or diminished to any degree; and there are abundance of things which cannot be represented to the life without it.

From an analysis of this *ink*, Dr. Lewis concludes that it contains an animal substance soluble in water, and consists of a black powder, mixed with some animal glue. He tried to imitate it, by mixing some lamp-black, prepared from linseed oil, by hanging a large copper pan over the flame of a lamp to receive its smoke, with as much melted glue as gave it sufficient tenacity for being formed into cakes. These cakes, when dry, answered

as well as the genuine Indian ink, in regard both to the colour, and the freedom and smoothness of working. Ivory black, and other charcoal blacks, levigated very fine, had the same effect with the lamp-black. It appears from three recipes for the preparation of Indian ink, in Du Halde's History of China, that the colouring material is lamp-black, to which is added, in one of them, a quantity of horse-chestnut, burnt till the smoke ceases. The coagulating matter, in one of the prescriptions, is a thin size of neat's leather; in another, a solution of gum tragacanth, and in the other, a mixture of size, with a decoction of certain vegetables, unknown to us. Du Halde observes, that the Chinese have inks of different goodness and price; that the most essential difference proceeds from the quality of the lamp-black, and that the best is the foot of oil, burnt in lamps, in apartments fitted up for this purpose.

The Chinese have often attempted to use this in their porcelains, to give the colour of black to the figures traced on white vessels, but it has been a vain attempt; for, however beautiful and strong the figures might appear when first laid on, and even when the vessels were dried, it all disappeared on the baking, and they came out quite white as they were put in. The colours for this use must be such as can penetrate the varnish, and endure the fire. Mineral colours are found to have these qualities, and the black alone therefore is to be employed; such light ones as this black burning off from the surface, and wholly disappearing. *Obs. sur les Coûumes de l'Asie*, p. 309.

INK is also an appellation given to any coloured liquor used in the same manner as black ink; as red, green, blue, yellow, &c. Red writing ink is prepared by infusing a quarter of a pound of the rasps of Brazil wood for two or three days in vinegar, boiling the infusion for an hour over a gentle fire, and afterwards filtering it, while hot, through paper laid in an earthen calender; then put it again over the fire, and dissolve in it, first, half an ounce of gum arabic, and afterwards slum, and white spirit, of each half an ounce. Red ink may be also made of vermillion, by beating together the glair of four eggs, a tea-spoonful of white sugar, or sugar-candy, powdered, and as much spirit of wine, till they be of the consistence of oil; then adding such a proportion of vermillion as will produce a red colour of sufficient strength; the mixture should be kept in a small phial, or well-stopped ink bottle, and well shook before it be used. Gum-water is often used instead of the glair of eggs; but this five made of singals, with a little honey, is much better for the purpose.

For red printing ink, see *PRINTING*.

Green ink may be made, by putting an ounce of powdered verdigris to a quart of vinegar, and straining the fluid, after it has stood two or three days: or, instead of this, the crystals of verdigris dissolved in water will answer the purpose; then dissolve in a pint of either of these solutions, five drams of gum arabic, and two drams of white sugar.

Blue ink is made by grinding indigo with honey and the white of eggs, and making it fluid with water.

Yellow ink is made by an infusion of saffron in water, with a little alum and gum arabic: or, by boiling two ounces of Avicenna, or French berries, in a quart of water, with half an ounce of alum, till one third of the fluid be evaporated, and then dissolving in it two drams of gum arabic, and one dram of sugar, and afterwards a dram of powdered alum.

In general, inks of all colours may be made by using a strong decoction of the ingredients used for dyeing, mixed with a little alum and gum arabic. See the several colours, *BLUE*, *GREEN*, &c.

INKS, *sympathetic*, or *secret*. Every sort of liquor with which a prison may write, so that the letters do not appear till there is some particular means used to give them a colour different from that of the paper, are called by the name of *sympathetic inks*; and of these there are great many kinds described in the writings of Baptista Porta, Lemery, and other authors.

All these inks may be regularly distributed into different classes, according to the different means which are to be used to make them appear; and these are in general the four following. 1. By giving a new liquor, or the vapour of a new liquor, a place on the paper, on which the letters are written with the naturally invisible ink. 2. By exposing the paper to the air, by which means the letters at first invisible will appear. 3. By passing gently over the letters a matter of some remarkable colour reduced to fine powder. And, 4. By exposing the paper to the fire.

This last is by much the best method, and is so general, that it may be prudently used to all papers suspected of containing any secret writing, as it seldom fails to discover it. All the common inks of this kind however, when

they have been once made to appear, either by fire or by any other method, can never be made to disappear again; but there is one kind described by Mr. Helot, in the Memoirs of the Academy of Sciences at Paris, and since tried many times with us, and elsewhere, which, though the letters it gives are in themselves invisible, and appear like those of some other of these inks, on their being held to the fire, yet they after that will fade and disappear on the paper again, and may be reproduced in this manner several times. This therefore is the first known ink of a fifth general class, of which future researches may discover perhaps more.

Of the first class of *sympathetic inks*, or those which do not appear till the paper on which they are written be made to imbibe another liquor, or the vapour of another liquor, are the following kinds.

To two or three parts of unslaked lime put one of yellow orpiment powder and mix the two, adding fifteen or sixteen times as much water as there was orpiment; stop up the phial with a cork and bladder, and let it in warm embers, shake the phial now and then for five hours, and finally decant the clear part, or rather filtrate it.

The room of this preparation may be used a saturated solution of common brimstone, made by boiling the brimstone either with quicklime, or in strong alkaline ley. In the mean time, burn a piece of cork thoroughly, and when well inflamed, quench it in common water, or rather in brandy. Being thus reduced into a friable coal, grind it with fair water, wherein gum arabic has been dissolved; and it will make a liquor as black as the common ink.

While these are doing, dissolve, in three times as much distilled or strong vinegar, over warm embers, a quantity of red sand, or of saccharum saturni, in thrice the quantity of water, for three or four hours, or till the liquor have a sweet taste. This liquor will be as clear as common water. Solutions of lead in aqua fortis answer the same end, except that, when written with, they are apt to corrode the paper.

The liquors thus prepared, write any thing on paper with this last sort, dry it, and nothing will appear. Over the place, write what you please with the second liquor; it will appear as if written with common ink: when dry, dip a small piece of rag or sponge in the first liquor, rub it over the written place, and the black writing will appear vanish; and that wrote with the invisible ink will appear black and legible. Again, take a book four or five inches thick, and on the first leaf write any thing with the last liquor; turn to the other end of the book, and rub there with a rag, dipped in the first liquor, on that part, as near as you can guess, opposite to the writing, and leave also the rag there, clapping a paper over it; then nimbly shutting the book, strike four or five smart strokes thereon with your hand, and turning the other side uppermost, clap it into a press, or lay it under a good weight for a quarter of an hour, or even half that time; then will the writing done with the invisible ink be found legible there. The above operation may be varied, by writing the invisible characters with the solution of bismuth in nitrous acid, and exposing them to the vapours of liver of sulphur, or moistening them with a solution of liver of sulphur.

Dissolve white or green vitriol in water, and writing with the solution, nothing will appear. Boil galls in water, and dip a linen rag in the decoction, and with it rub the place before writ, and it will appear black and legible. Rub it over again with spirit of vitriol, or its oil, and the writing will disappear again; rub it over again with oil of tartar per deliquium, the letters will appear again, but of a yellow colour. If the blackness of ordinary ink be destroyed by a sufficient quantity of nitrous acid, the writing made by it will remain invisible till it be moistened with liquid fixed alkali.

The golden *sympathetic ink*. This is made by dissolving in aqua regia as much gold as that menstruum can take up, and then adding to the liquor five or six times as much water; in another vessel there must be some tin dissolved in aqua regia; and when that menstruum has also taken up as much of the metal as it can, there is to be added to it an equal quantity of common water. The letters must be written on white paper with the solution of gold, and the writing being dried in the shade, the letters will not appear, at least not for seven or eight hours afterwards; dip a pencil in the solution of tin, and rub that over the solution of gold with which the letters were written, and they will appear of a beautiful purple. It might be supposed, that any other metals which were soluble in the same acid menstruum would equally produce this effect; but experiment shews, that this is not the case; and silver and copper, though both soluble in aqua fortis, yet produce no change of colour by these precipitations made by mixing the solutions of them on paper;

paper; and this example of such an effect in the solutions of gold and tin, is an exception to the general rules in the solutions of metals, and their effects on one another.

The purple colour of these letters may be again effaced by rubbing some simple aqua regia over the paper, and may be made to appear again by rubbing over that the solution of tin. Kunkel, Callius, and Orschal, with some other writers, made the first steps towards this discovery, by their attempt to give crystal, by means of gold, the colour of the oriental rubies. There are beside these mineral preparations some vegetable ones, which give the same phenomena, but these are the more certain.

Of the second kind of *sympathetic ink*, or those which appear on being exposed only to the air, is the golden *ink* made by adding to a solution of gold in aqua regia, so much water that the liquor shall not stain a white paper; letters written with this will not appear till the paper has been exposed some hours to the open air, and they will then begin to acquire a colour by degrees, till they at length become of a deep violet colour, tending to black. If, instead of exposing the paper to the air, it be kept in a box close shut up, or closely folded in other paper, it will remain invisible two or three months; but at the end of that time it will begin to appear, and will by degrees become of a deep violet colour. So long as the gold remains united to its solvent, it is yellow; but the acid that dissolves it being of a volatile nature, the greater part of it evaporates, and leaves no more than is just necessary to colour the scale of gold which remains upon the paper.

The second of these is the silver *ink*, made by a solution of silver in aqua fortis, weakened by distilled water, till it will not stain the paper. Letters written with this will be invisible for three or four months, if that up in a box; but if they be exposed to the sun they become legible in about an hour, because by this means the evaporation of the acid is accelerated. The letters written with this *ink* are of a slate colour; and that from the sulphurous nature of the aqua fortis, every thing that is sulphurous blackening silver. This blackish colour, however, is not permanent; for the sulphurous part finally evaporates, the letters are left to their natural appearance, and are of a true silver colour, if the silver that was used was fine, and the place open.

In this class there may also be placed several metallic dis-solutions; as that of lead in vinegar, and of copper in aqua fortis, which give at length a brownish colour upon the paper; as also the solution of tin in aqua regia, or mercury in aqua fortis, of iron in vinegar, of emery and several of the pyrites in spirit of salt. But all these, though they give letters which are after some time legible, on being exposed to the air, are also made to appear instantly on the paper, on holding them to the fire. Each of these solutions gives its own particular colour; but they have all this disadvantage, that in time they eat away the paper, and the letters are lost in the shape of so many holes.

Of the third class of *ink*, or that which appears on rubbing over the paper with a brown or black powder, are almost all the glutinous expressed juices of plants, which are themselves of no remarkable colour, the milk of animals, or any other thick and viscous fluids. To use these, the letters must be written on a white paper, and when dry, there is to be thrown over them the fine powder of any coloured earth, or other such substance; and the writing will afterwards appear coloured, because its viscous quality remains sufficiently in it for the entangling and retaining this fine powder, though it falls easily off from every other part of the paper. Mem. Acad. Science. Par. 1737.

Of the fourth class, or those *ink* which become visible on holding them to the fire, there are a vast number; and indeed all infusions, the matter of which is readily burnt to a sort of charcoal by a little fire, will answer this purpose. The nicest of this kind is the sal ammoniac *ink*, made by dissolving a scruple of sal ammoniac in two ounces of fair water. Letters written with this solution are invisible on the paper, till it is held before the fire, or has an iron a little heated passed over it. The rationale of this is, that the inflammable part of the sal ammoniac is burnt to a charcoal by a heat which is not sufficient to scorch the paper; and this is the case with all the rest of this class. The letters written with this solution are, however, of no great duration; for the salt being apt to moisten in the air, the letters soon spread, and run together in a confused manner.

Dr. Lewis says, that all the salts which he has tried produce this effect in a greater or less degree; nitre, alum, tartar, very weakly; sea-salt more strongly; fixed alkaline salts still more so; but sal ammoniac the strongest of all. Metallic solutions, made in acids, and diluted to as

not to corrode the paper, act in the same manner. The juice of lemon and milk have also been used as *sympathetic ink*, the writing with which appears upon the application of heat sufficient to decompose the oily and mucilaginous parts of these liquors.

The fifth class of *sympathetic ink* contains only one yet known kind.

This, though in itself invisible, becomes of a bluish green when held in the fire; and this colour disappears again as the paper cools, and is to be produced again on holding it again to the fire; and this for a long time, and a repeated series of trying. It may also, according to the different manner of treating it, be made to appear blue, green, yellow, red, and of some other colours. This property of the tinging matter of bismuth ore was published at full length by a German lady, in 1705.

A certain German chemist thence the academy at Paris a salt of rose-water, which became blue on holding it to the fire, and at the same time showed the ore from which he procured the salt, which he called an ore of murexite, a name given by many to the bismuth ore. He added, that this was the mineral from which the fine blue enamel of Sneeberg was prepared, and that no other ore but this afforded it, and that he made the tincture from this mineral with aqua fortis, which he fixed with sea-salt.

This was the substance of what the German declared, and from which Mr. Hellot, in 1736, took the hint for his discovery of this remarkable *ink*. The salt was, after many experiments, at length found to be produced from an arsenic ore; and it was found, that all the cobalts and ores of bismuth afford a tincture capable of these changes by fire.

The method of preparing it is this: pour upon two ounces of arsenic ore, grossly powdered, a mixture of five ounces of aqua fortis, and five ounces of common water. After the first ebullition is over, place the vessel in a gentle sand-heat, and let it stand there till no more air-bubbles seem to ascend; after this increase the fire, so as to make the liquor boil for about a quarter of an hour; after this the liquor will become of a reddish colour, and when cold it is to be decanted clear off from the sediment into a phial; and after standing in that some time, it is to be again decanted off from what is precipitated there; and so on for three or four times, till it is quite clear; for it must not be filtered, lest the acid should take something from the paper that might spoil the effects. When the liquor is clear, there must be added to it two ounces of white sea-salt; this mixture is to be evaporated over a gentle sand-heat, till there remains only a dry saline mass. When the liquor is grown hot, it changes from its orange-colour to a fair red; and when the aqueous humidity is evaporated, in becomes of a beautiful emerald colour, and from this, as it dries up, it changes by degrees to a dirty green, like that of verdigris in the cake. As it becomes nearly dry, it must be stirred about with a glass rod or pebble, to keep it from uniting into a mass; and it must not be kept over the fire till perfectly dry, because by that means the colour is often lost, and the salt from green becomes of a dusky yellow; but if it be taken from the fire while it is green, it gradually becomes reddish as it cools, and finally is of a rose-colour.

The manner of using this *sympathetic ink*, is this: write with it on a fine and smooth paper, or draw with a black-lead pencil the figure of a plant or tree on the paper; then trace over the same lines with this liquor; let it dry in the open air, and then rub off the black lines with bread, and the paper will appear altogether fair, though the lines made by the *ink* are in reality sunk deep into it. On holding this paper to the fire the lines will all appear, and the figure of the plant or the letters will be painted in a beautiful bluish green, which will continue so long as the paper is warm; but when it is cold again, they will wholly disappear. The lines, therefore, disappear much sooner in winter than in summer; and in very hot weather it is often necessary to lay the paper on a marble, or other very cold body, in order to produce this effect. At any time, if the paper be scorched in the experiment, the colour of the lines will not disappear again, even if ice be laid upon them. If the writing be exposed for three or four days to a humid air, the lines will appear of a fine pale red. If the impregnation of the ore of bismuth, instead of sea-salt, have alum added to it, and the whole process be continued as before described; and if letters be written with the red liquor as it is taken out of the vessel, the letters will not appear even on holding it to the fire; but if the paper be wetted over with a clear solution of marine salt, and then left to dry, and afterwards held to the fire, the letters will appear blue. The same also will be the effect, if the writing be exposed to the vapour of hot spirit of salts. When this preparation is thus made with alum, instead of common salt, the liquor never becomes green, but continues red, and never

never changes colour in the drying, or afterwards. The green colour seems to be wholly the effect of the sea-salt, for not only this aluminate impregnation, but others in which other salts had been employed, were always found to be of a different colour.

Glauber's salt used instead of common sea-salt, left the mals red in the same manner as alum did. Nitre added, instead of sea-salt, gave the precipitate, or dried salt, a beautiful purple colour, which became white on the instant that water was poured upon it, and a rose-coloured tincture was drawn from it, which gave lines or letters on paper, which continued invisible as long as they were cold, but assumed a beautiful red on holding the paper to the fire; which colour they retained no longer than while the paper continued warm, disappearing afterwards in the same manner with the green colours made by the sea-salt; and if a simple solution of sea-salt be rubbed over the paper, and suffered to dry, and the paper be afterwards heated, the lines appear blue. Borax has the same effect in this preparation with the nitre. All these experiments were made with the neutral salts; but in order to try what would be the effects of alkalies in the mixture, Mr. Hællot added to three ounces of the impregnation of the ore in aqua fortis, pure salt of tartar, till the ebullition ceased; but the consequence of this was no great precipitation, but merely the subsiding of a small white sediment; this mixture being evaporated nearly to a dryness, the remaining mass, so long as it was warm, appeared of a beautiful purple; but this became paler as it dried, and turned white in an instant on pouring water upon it. This, dissolved in water in the manner of the others, gave lines on paper of a faint rose-colour, which appeared or disappeared in the manner of those made by the other solutions, according as the paper was hot or cold; and the wetting the paper with a solution of sea-salt, had the same effects on this as on the others, making the lines appear blue on holding to the fire. Mem. Acad. Par. 1737. See Colours from METALS.

This ink may be easily made by digesting zaffre, commonly sold by druggists, in aqua regia; and thus is obtained the soluble part of zaffre, which is the calc of cobalt. This solution is then to be diluted with a little common water. In exposing the paper written with this solution to the fire, care must be taken not to heat it too much; for in this case, the writing will not again disappear by exposure to cold. This ink, says the author of the Chemical Dictionary, may be applied to the drawing of landscapes, in which the earth and trees, destitute of verdure, being drawn with common ink, give a prospect of winter; and which may be made to assume the appearance of spring, by exposure to a gentle heat, which covers the trees with leaves, and the earth with grass, by rendering visible those parts of the landscapes which are drawn with this sympathetic ink; and, as the solution of regulus of cobalt or zaffre in spirit of nitre acquires a reddish colour by the application of heat, the red solution might be contrived to represent the fruits and flowers.

INK-FISH, in Ichthyology. See CUTTLE-FISH, and SERP.

INLAWING, *Inlegatus*, a relaxing of one out-lawed to the protection of the law, and benefit of a subject.

The word comes from the Saxon *inlegian*, i. e. *inlagora*.

Terms of Law.

INLAW, *Inlegatus*, he that is of some *frank-plage*, and not out-lawed. It seems to be the contrary to *outlaw*.

INLAND implies any thing situate in the main land, or heart of a country, far from the sea-coast.

Hence inland bills, in traffick, are such bills as are payable in the same land wherein they are drawn. See BILL.

INLAYING. See VENEERING, MOSAIC, and MARQUETRY.

INLEADED, in our Old Friery, signifies entangled or enmeshed. It is used in the champion's oath. 2 Inst. 247. Blount.

INLISTING, in a military sense. See LISTING.

INMATES, such persons as are admitted, for their money, to live in the same house or cottage with another man, in different rooms, but going in at the same door; being usually supposed to be poor, and not able to maintain a whole house themselves. These are inquirable in a court-leet.

No owner or occupier of a COTTAGE shall suffer any *inmates* therein, or more families than one to inhabit there, on pain of forfeiting ten per month to the lord of the leet.

INN, a place appointed for the entertainment and relief of travellers.

Inns are licensed and regulated by justices of the peace, who oblige the landlord to admit into recognizances for keeping good order. See ALMOUSERS.

If a person who keeps a common inn, refuses to receive

a traveller into his house as a guest, or to find him victuals and lodging, on his rendering him a reasonable price for them, he is liable to an action of damages, and may be indicted and fined at the king's suit. By the yearly acts against mutiny and sedition, the constable, and in his default a justice of the peace, may quarter soldiers in *inns*, livery-stables, ale-houses, and victualling houses. The rates of all commodities sold by *inn-keepers*, according to our ancient laws, may be assessed; and *inn-keepers* not selling their hay, oats, beans, &c. and all manner of victuals, at reasonable prices, without taking any thing for litter, may be fined and imprisoned, &c. by 21 Jac. 1. cap. 21. Where an *inn-keeper* harbours thieves, persons of infamous character, or suffers any disorders in his house, or sets up a new *inn* where there is no need of one, to the hindrance of ancient well-governed *inns*, he is indictable and finable; and by statutes such *inn* may be suppressed. Action upon the case lies against any *inn-keeper*, if a theft be committed upon his guest by a servant of the *inn*, or any other person not belonging to the guest; though it is otherwise where the guest is not a traveller, but one of the same town or village; for in that case the *inn-keeper* is not chargeable; nor is the master of a private tavern answerable for a robbery committed on his guest. It is said that even though the travelling guest does not deliver his goods, &c. into the *inn-keeper's* possession, yet if they are stolen he is chargeable. An *inn-keeper* is not chargeable for any thing out of his *inn*, but only for what is within it; yet where he of his own accord puts the guest's horse to grass, and the horse is stolen, he is answerable; he not having the guest's orders for putting such horse to grass. The *inn-keeper* may justify stopping the horse, or other things of his guest, for his reckoning; and may detain the same until it be paid. Where a person brings his horse to an *inn*, and leaves him in the stable, the *inn-keeper* may detain him until such time as the owner pays for his keeping; and if the horse eats out as much as he is worth, after a reasonable appraisement made, he may sell the horse, and pay himself. But when a guest brings several horses to an *inn*, and afterwards takes them all away, excepting one, this horse is left may not be held for payment of the debt of others; for every horse is to be sold, only to make satisfaction for what is due for his own meat.

Any person found tipping in an *inn*, is adjudged within the statutes against DRUNKENNESS; and *inn-keepers*, or alehouse-keepers, permitting tipping in their houses, are liable to the penalty of 10s. &c. by 1 Jac. cap. 9. 1 Car. cap. 4. 21 Jac. cap. 7.

INNS. Our colleges of municipal or common law professors and students, are called *inns*; the old English word for houses of noblemen, bishops, and others of extraordinary note, being of the same signification with the French word *hotel*.

Inns of court are so called, as some think, because the students there are to serve and attend the courts of judicature, or else, because anciently these colleges received more but the sons of noblemen, and better sort of gentlemen, who were here to be qualified to serve the king in his court; as Fortescue affirms. And in his time, he says, there were about two thousand students in the *inn* of court and chancery, all of whom were *filii militum*, or gentlemen born. But this custom has gradually fallen into disuse; so that in the reign of queen Elizabeth, Sir Edward Coke does not reckon above a thousand students, and the number at present is very considerably less; for which Judge Blackstone assigns the following reasons. 1. Because the *inns* of chancery being now almost totally filled by the inferior branches of the profession, are neither commodious nor proper for the resort of gentlemen of any rank or figure; so that there are very rarely any young students entered at the *inns* of chancery. 2. Because in the *inns* of court all sorts of regimen and academical superintendence, either with regard to morals or studies, are found impracticable, and therefore entirely neglected. Lastly, because persons of birth and fortune, after having finished their usual courses at the universities, have seldom leisure or resolution sufficient to enter upon a new scheme of study at a new place of instruction; whereas few gentlemen now resort to the *inns* of court, but such for whom the knowledge of practice is absolutely necessary in such as are intended for the profession. Comm. book 1. p. 25.

Our *inns of court*, justly famed for the production of men of learning in the law, are governed by masters, principals, benchers, stewards, and other officers; and have public halls for exercises, readings, &c. which the students are obliged to attend, and perform for a certain number of years, before they can be admitted to plead at the bar. These societies have not, however, any judicial authority over their members; but instead of this they have

have certain orders among themselves, which have by consent the force of laws. For lighter offences persons are only admonished, or put out of common; for greater, they lose their chambers, and are expelled the college; and when once expelled out of one society, they are never received by any of the others. The gentlemen in these societies may be divided into benches, utter-barristers, inner-barristers, and students.

The four principal *inns* of court, are the Inner Temple and Middle Temple, heretofore the dwelling of the Knights Templars, purchased by some pious persons of the common law about three hundred years ago; Lincoln's *Inn*, and Gray's *Inn*, anciently belonging to the earls of Lincoln and Gray. The other *inn* are the two Serjeants' *Inns*.

Inns of chancery were probably so called, because anciently inhabited by such clerks as chiefly studied the forming of writs, which regularly belonged to the curriers, who are officers of CHANCERY.

The first of these is *Thavies Inn*, begun in the reign of Edward III. and since purchased by the society of Lincoln's *Inn*. Beside this we have *New Inn*, *Simond's Inn*, *Clement's Inn*; *Clifford's Inn*, anciently the house of the lord Clifford; *Staple Inn*, belonging to the merchants of the staple; *Town's Inn*, anciently a common *inn* with the sign of the lion; *Furnival's Inn*, and *Bernard's Inn*.

These were heretofore preparatory colleges for younger students; and many were entered here, before they were admitted into the *inn* of court. Now they are mostly taken up by attorneys, solicitors, &c.

They all belong to some of the *inn* of court, who formerly used to send yearly some of their barristers to read to them.

INN, or **INNER**, in the *Mosaic*, is applied differently, according as the work works to the right or left upon the volute, or as he works along by a wall, a hedge, or the like. For along or by a wall, the leg that is of a file with, or next the wall, is the outer, and the other the *in* or *inner* leg. And if upon volute, the work works to the right, the right heel is the *inner*, and the left the outer heel, and to the left of the other parts of the body, furniture, &c. The direct contrary of this will happen, if the work works to the left.

INNATE *virtus*. See **AIX**.

INNATE *force*. See **VIS** *influx*.

INNATE *heat*. See **HEAT**.

INNATE *idea*, or *proprie*, are certain primary notes or characters, by many supposed to be stamped on the mind of man when it first receives its being, and which it brings into the world with it.

But the doctrine of *innate* ideas is abundantly confuted by Mr. Locke. See **IDEA**.

INNER *barrenness*. See **BARREN**.

INNINGS, lands recovered from the sea, by draining and banking.

INNOCENTS *day*, the name of a feast celebrated on the twenty eighth day of December, in commemoration of the infants murdered by H. I.

Heretofore it was the custom to have dances in the churches on this day, wherein were persons who represented bishops, by way of derision, as some suggest, of the episcopal dignity; though others, with more probability, suppose it done in honour of the innocence of childhood. See **RECTOR'S** *parson*.

By a canon of the council of Constance, held in 1760, these were expressly forbid; but they were not wholly suppressed, at least in France, before the year 1424, when the doctors of the Sorbonne addressed a spirited letter on this subject to all the bishops of the kingdom.

INNOMINATA *arteria*, is the external branch of the external iliac artery, at its division about the hole in the ligamentum Poupartii. It ascends outwardly to the umbilicus of the spine of the ilium; it is lost in the muscles of the belly, and it sends branches to the iliacus internus. See **ILIO** *costalis*.

INNOMINATA *ossis*. See **OSTEA** *innominata*, under **OS**.

INNOMINATI, **GH** **INNOMINATI**, *dwynni*, persons who have no names, a title by which the academists of Parma distinguish themselves.

Most cities in Italy have an academy, and each has its proper name. Thus, those at Parma entitle themselves *Gh' innominati*, as if it was their character to have no name at all.

INNOMINATUM, in general, signifies any thing without a name.

Many parts of the body are left under this indistinct term; as the *innominata glandula acris*, now called *caruncula*; *arteria innominata faciei*, &c. See **EVIL**.

O **INNOMINATI** is the other fish called *scorpa*, or *scorpa*, being composed of three bones, viz. the **ILIO**, the **PUBIS**, and **ISCHIUM**, only connected by cartilages. See **TAB. ANAT. (Osteol.)** fig. 3. n. 16, 17, 18, 19. See **OS**.

VOL. II N° 186.

INNOVATION, in *Law*. See **NOVATION**.

INNUENDO, of *innuendo*, *innuendo*, is a word frequently used in writs, declarations, and pleadings, to ascertain a person or thing which was named, but left doubtful, before; as, he *innuendo* the plaintiff did so and so; mention being before made of another person. In common conversation or writing, an *innuendo* denotes an oblique hint, or distant reference, in contradistinction to a direct and positive charge.

INOCULATION, or **BEDDING**, in *Agriculture* and *Gardening*, a kind of grafting, or an artificial operation, by which the bud of one fruit-tree is set into the stock or branch of another, so as sometimes to make different sorts of fruit grow in the same trees. See **ENGRAFTING**.

There are various ways of performing this: the ancient method was, by making a shallow incision in the bark, where the knot of a shoot or eye, *sway* (whence the operation takes its name), begins to bud forth; into this a promising shoot of another kind was inserted, and the incision closed up with fat earth or clay.

Peaches, nectarines, cherries, plums, &c. as also oranges and jessamines, succeed very well this way, and it is indeed preferable to any other for fruit-trees in general.

The method of performing it is this: the operator must be provided with a sharp pen-knife, having a flat half, the use of which is to raise the bark of the stock, to admit the bud, and some found buds may, which should be soaked in water to increase its strength, and make it more pliable; then having taken off scumings from the trees to be propagated, a smooth part of the stock must be chosen, which, if intended for *dwars*, must be about five or six inches above the ground; but if for standard, it should be as many feet high. A horizontal cut is then to be made across the root of the stock, and from the middle of that another slit must be made straight downward of two inches in length, that the whole may have the figure of the letter T, but these must not be cut too deep. Then cutting off the leaf from the bud, and leaving its foot-stalk remaining, a cross cut is to be made on it about half an inch below the eye, and the bud is to be slit off with part of the bark to it, in form of an *escutcheon*. The wood then must be taken out of the slip of the bud, without pulling the eye of the bud out with it; for if this happens, the bud must be thrown away as incapable of succeeding. When the bud is thus prepared, the bark of the stock is to be gently raised with the flat half of the pen-knife, and the *escutcheon* of the bud must be slipped in, and placed very evenly between the bark and the wood, cutting off any part of the kind of the bud which may be too long for the slit made in the stock. The whole is then to be gently tied up with the bast mat, beginning at the lower part of the slit, and taking great care not to injure the eye of the bud, which is to be left out at the slit. In three weeks or a month the bud will show that it is joined; and when the tying round the stock must be loosened; and in the March following, the stock must be cut off about three inches above the bud, supposing that the wet may run off. To this part of the stock the shoot proceeding from the bud is to be tied, but the winds should loosen or displace it; and when the tree has stood one year in this state, the stock must be cut down close to the bud.

The season for *inoculating* is from the middle of June to the middle of August, according to the forwardness of the trees. When the buds are formed at the ends of the shoots of the same year, it is a proof that the tree is fit for the purpose; the first tree that comes in season to be *inoculated* is the apricot, and the last the orange-tree; and in using this, choice should always be made of a cloudy day, that the sun may not dry up the buds too quick; and in some very tender plants, a part of the wood in the *escutcheon* of the bud should be left in. Miller.

This practice has the advantage of engrafting in many respects, both as it is more secure, it seldom failing of having effect, especially if two or three buds are put into the same stock, and as its success is more readily discovered. Indeed, when large stocks are to be provided on, *inoculation* is not proper, and they are then obliged to have recourse to grafting.

This rule is observed to hold universally, viz. that no success is to be expected in *inoculation*, if the sap does not run well; that is, if the bark will not part readily from the wood of the stock.

It is said by many, that such trees as are *inoculated* in the month of February, will continue always free from worms, both themselves and their fruit; but this is a thing not confirmed by experience. Another error in these things is, the opinion that a cyon taken from a young tree which has never yet blossomed, will never bear fruit; experience proves that it will; but our gardeners choose rather to take their cyons from such trees as have already borne. Phil. Trans. N° 2.

In the *insulations* made upon fruit-trees, it is observable, that a little vegetable bud, often not so big as a pea, is able to transmute all the sap which arrives at it, that through this sap be already in the root, and in its passage upwards, determined by nature's intention, as is said, to the production of fruit natural to the stock, it should yet, by so small a vegetable substance, be so far changed as to constitute a fruit quite otherwise qualified than the genuine product of the tree; which at the same time is actually produced by those other portions of the like sap, that happened to nourish such prolific buds as are the genuine offspring of the stock; so that the same sap, which in one part of the branch constitutes a cluster of haws, in another part of the same branch may constitute a pear. And what is further remarkable, not only the fruits made of the same sap often differ from one another in shape, figure, colour, odour, taste, and other obvious qualities, but though the sap itself be a watery and almost insipid liquor, yet it is not only convertible by buds of several orders into different fruits, but in one and the same fruit, the transmuted sap shall by different textures be made to exhibit very different, and sometimes contrary, qualities. As when a peach-bud not only changes the sap which comes to it, into a fruit very different from that which the stock naturally produces, but into parts very different from one another in the same fruit.

From *insulation* therefore we learn, that a liquor seemingly homogeneous, may, by being variously strained, be transmuted into bodies endowed with new scents, colours, tastes, solidity, medicinal virtues, and many other qualities, manifold and occult. Boyle's Works *air*, vol. i. p. 250.

INOCULATION, in a physical sense, is used for the transplantation of distempers from one subject to another, particularly for the engraving of the small-pox; which is a new practice among us, but of ancient use in the eastern countries.

INOCULATION, its history. It is well observed by the Baron Dimsdale, that accident hath furnished the art of medicine with many valuable hints; and some of its greatest improvements have been received from the hands of ignorance and barbarism. This truth is remarkably exemplified in the practice of *insulation* of the small-pox; but to the honour of the English physicians, they measured not the value of this practice by the meanness of its origin, but by its real importance and utility: they patronized a barbarous discovery with no less zeal and affection than if it had been their own. Indeed, the whole nation might be said to have adopted the practice, for the greatest encouraged it, by becoming examples; and the wisest were determined by the general event of the method.

As to the origin of the art of *insulating* the small-pox, as well as the time and place in which it was performed, they are equally unknown to all by whom the practice is adopted. Accident probably gave rise to it: Pylarini says, that among the Turks it was not attended to, except among the meaner sort. Dr. Ruell informs us in the Philosophical Transactions, vol. lviii. p. 142, that no mention is made of it by any of the ancient Arabian medical writers that are known in Europe; and the physicians who are natives in and about Arabia, assert, that nothing is to be found regarding it in any of those of a more modern date. He further says, that he engaged some of his learned Turkish friends to make enquiry; but they did not discover any thing on this subject of *insulation* either in the writings of physicians, historians, or poets. Until the beginning of the eighteenth century, all the accounts we have of *insulating* the small-pox are merely traditional. The silence on this subject, observed amongst writers in the countries where the practice obtained, Dr. Ruell supposes, with great probability, to be owing to the physicians there never countenancing or engaging in it. It is also remarkable, that before Pylarini's letter to the Royal Society in 1701, nor yet for several years after, this practice is not noticed by any of the most inquisitive travellers. On this Dr. Ruell very justly observes, that customs the most common in distant countries, are often the least apt to attract the observation of travellers, who, engaged in other pursuits, must be indebted to accident for the knowledge of such things as the natives seldom talk of, upon the belief that they are known to all the world.

The first accounts we have in the learned world concerning *insulation*, are from two Italian physicians, viz. Pylarini and Tinnini, whose letters on the subject may be seen in the Philosoph. Transact. *air*, vol. v. p. 370, &c. The first is dated A. D. 1701; the next is dated A. D. 1712. Whether our enquiries are extended abroad, or confined to our own country, *insulation* hath been practised under one mode or other, time immemorial; in

Great Britain, and its adjacent isles, we have well authenticated accounts, extending farther backward than any from the continent. Dr. Williams of Haverfordwell, who wrote upon *insulation* in 1725, proves, that it had been practised in Wales, though in a form somewhat different, time out of mind. Mr. Wright, a surgeon in the same place, says, that buying the small-pox is both a common practice, and of long standing in that neighbourhood. He says, that in Pembrokeshire there are two large villages near the harbour of Milford, more famous for this custom than any other, viz. St. Ithmael's, and Marloes. The old inhabitants of these villages say, that it hath been a common practice; and that one William Allen of St. Ithmael's, who in 1712 was ninety years of age, declared to some persons of good sense and integrity, that this practice was used all his time; that he well remembered his mother's telling him that it was a common practice all her time, and that he got the small-pox that way; so that at least we go back a hundred and sixty years, or more.

In the Highlands of Scotland, and some of the adjacent isles, Dr. Alexander Monro, senior, informs us, that the custom through ages past hath been, to put their children to bed with those who laboured under a favourable small-pox, and to tie worsted threads about their children's wrists, after having drawn them through various pulvules.

According to the result of Dr. Ruell's enquiries, the Arabians assert, that the *insulation* of the small-pox has been the common custom of their ancestors, and that they have no doubt of its being as ancient as the disease itself. It is remarkable, that buying the small-pox is the name universally applied in all countries to the method of procuring the disease; it is true, that there are other terms; but in Wales and Arabia, as well as many other countries, this is the usual appellation. From the sameness of the name, and the little diversity observable in the manner of performing the operation, it is probable that the practice of *insulation* in these countries was originally derived from the same source. From its extensive spread, it is probably of great antiquity too.

In the year 1717, lady Mary Wortley Montague, wife of the English ambassador at Constantinople, had her son *insulated* there at the age of six years; he had but few pustules, and soon recovered. In April, 1721, *insulation* was successfully tried on seven condemned criminals in London, by permission of his majesty. In 1722, lady Mary Wortley Montague had a daughter of six years old *insulated* in this island; soon after which, the children of the royal family, that had not had the small-pox, were *insulated* with success; then followed some of the nobility, and the practice soon prevailed. And here we date the commencement of *insulation* under the direction of art.

From the example of the royal family in England, the practice was adopted in Germany, particularly in Hannover, and its adjacent countries.

After Mr. Maitland had succeeded with those he had *insulated* in and about London, he introduced the practice into Scotland, in the year 1726.

Sweden soon followed the example of the English; and Russia at this time is engaging one of our principal promoters and improvers of this art. And now there are not many countries that do not more or less engage in it.

INOCULATION, different modes of. The practice of *insulation* hath obtained in every part of the world. It may be grateful, at least to curiosity, to be informed of the different modes that are, and have been, of communicating the infection from the small-pox.

Insulation with the blood of variolous patients hath been tried without effect: the variolous matter only produces the variolous disease.

The application of the variolous matter takes place in a sensible part only; the activity of the virus is such that the smallest atom, though imperceptible to any of our senses, conveys the disease as well as the largest quantity. Hence, the most obvious method is the prick of a needle, or the point of a lancet dipped in the matter of a variolous pustule.

Cotton, or thread is used, that are previously rubbed with powdered variolous scabs; this thread is drawn with a needle through the cutis, but not left in. This is the method in some parts of the East Indies. The Indians pass the thread on the outside of the hand, between any of the fingers, or between the fore-finger and thumb. The Thaisian women *insulate* in the forehead and chin. Some scratch the skin thin, and rub in the powdered dry scabs which fall from the pustules of patients with the small-pox.

Many of the Greek women make an oblique puncture with a needle, on the middle of the top of the forehead, on each cheek, the chin, each metacarpus, and each metatarsus;

tartarus; then drop in each a little of the pus just taken warm from a patient, and brought in a servant's bosom. Others in Greece make several little wounds with a needle in one, two, or more places in the skin till some drops of blood ensue; then the operator pours a drop of warm pus fresh from a pustule, and mixes it with the blood as it issues out; then the wound is covered by some with a bandage, by others with half a walnut-shell, placed with its concave side over each orifice.

The Chinese convey a pellet of variolated cotton, with the addition of a little milk, into the nostrils of the patient; they collect dry pustules, and keep them in a porcelain bottle well corked; and when they inoculate, they mix a grain of muck with three or four grains of the dry scales, and roll them in cotton. This method may be called *inoculation*.

About Bengal, in the East Indies, the person who intends to be inoculated, having found a house where there is a good sort of the small-pox, goes to the bed of the sick person, if he is old enough; or if a child, to one of his relations, and speaks to him as follows: "I am come to buy the small-pox." The answer is, "Buy if you please." A sum of money is accordingly given, and one, three, or five pustules, for the number most always be odd, and not exceeding five, are extracted whole, and full of matter. These are immediately rubbed on the skin of the outside of the hand between the fore-finger and the thumb; and this suffices to produce the disease. The same custom obtains in Algiers, Tunis, Tripoli and other countries.

Very similar to the custom among the people about Bengal, &c. is that in Arabia, where, on some ill-fated party they make several punctures with a needle imbued in variolous matter, taken from a pustule of a favourite kind. Here they buy the small-pox too, as follows: the child to be inoculated carries a few raisins, dates, sugar-plums, or such like; and shewing them to the child from whom the matter is to be taken, asks, how many pocks he will give in exchange? The bargain being made, they proceed to the operation; but this buying, though still continued, is not thought necessary to the success of the operation. The Arabs say that any fleshy part is proper; but generally they insert the matter between the fore-finger and thumb on the outside of the hand.

The Georgians insert the matter on the fore-arm. The Armenians introduce the matter on the two thighs. In Wales, the practice may be termed *infriction* of the small-pox. There, some of the dry pustules are procured by purchase, and are rubbed hard upon the naked arm or leg.

The practice in some places is to prick the skin between some of the fingers by means of two small needles joined to one another; and after having rubbed a little of the matter on the spot, a circle is made by means of several punctures of the bipoints of a common pin, and matter is again rubbed over it. The operation is finished by dressing the wound with lint.

Another custom is to mix a little of the variolous matter with sugar, and give it to be drank in any agreeable liquor.

Incisions have been made in the arms and legs, and thread, cotton, or lint, previously dipped in the variolous matter, was lodged in them.

The practice of some is to bathe the feet in warm water, and then secure lint dipped in the variolous matter, on the instep, or other part of the foot, where the skin is thin.

Others apply a small blistering plaster; and when the scarf skin is elevated and lapped off, the variolous matter is applied to the surface of the true skin, and confined there by a little lint or plaster.

Scratching the skin with a pin or needle, and then rubbing the part with lint, previously dipped in variolous matter, is the custom in some places.

In the Highlands of Scotland they rub some part of the skin with fresh matter, or dip worsted in variolous matter, and tie it about the children's wrists. They observe, that if fresh matter is applied a few days successively, the infection is more certain than by one application.

INOCULATION, objection to, answered. 1. It is not lawful to save life, or to destroy it? Luke vi. 9. And as it is a difficulty with many serious people, whether to admit of this practice or not, this objection should be considered in a religious view. We should in this case remember, that as the fall of man brought the danger of diseases into the world, so to evade, oppose, or destroy it, is not only his right, but duty, if in his power. And if events imply the cause, a long run of uninterrupted success implies an efficacious remedy. Though some die under this management, it is sufficient to prove the lawfulness of a remedy, that it is proper for, and hath by experience been found in most cases effectual to the end

for which it was used. When danger surrounds the ill conduct is more proper than to enquire into, and pursue the means of escape. To neglect our safety is to risk below the brutes, who by instinct avoid the evil to which they are exposed. *Inoculation* is a means of saving life in many instances, and of moderating the severity of affliction in more. Willingly then to neglect the means of saving life is to be guilty of murder.

2. It is bringing a distemper on ourselves, and so usurping the sacred prerogative of God.

As to the first part of this objection, if by distempers are meant sickness and pain, that is practised daily in other instances, in concurrence with the Scripture dictate, viz. of two evils chuse the least. But the supposition of objections in this instance is not altogether true; for, by *inoculation*, a disease is not properly said to be communicated; it only excites and frees us from one, which, though latent, is already in us; or, which in effect is the same, *inoculation*, by an advantageous mode of infusing, &c. frees the patient in all instances from the usual difficulties of the disease; *saves the life* of most who submit to it; and with the natural small pox it *destroys that disposition* in the body, without which the disease cannot take place. It is owned that some hazard attends it; it is sometimes mortal, and indeed it is fit it should be so; it is generally successful, that encourages us to proceed; it sometimes, though rarely fails; hence we are cautious and careful, and led to act with a dependence on him, to whom belong the issues from death.

Respecting the offence given to God; a reliance on Providence does not imply that we are not to prevent or oppose the evils which we foresee, and which we have in our power to guard against by prudent precautions. Would these objections, in other instances, refuse the means of lessening the malignancy and danger of disease, than which the practice of *inoculation* is no more? Let the adherents of the rights of God say, whether, when God permits the discovery of preserving ourselves from an impending evil, he forbids our using it? If our Maker offers us a remedy, it is offending him to reject it. 3. The decrees of God have fixed the commission of every disease, and our precautions cannot prevent what he hath determined.

However true it is, that our days are determined, &c. yet it is God's revealed will, and not his secret purposes which we are to regard as the rule of duty. God hath required of us to have a tender regard to our lives; and those who disobey him herein, are guilty of a degree of self-murder, and will never be acquitted of that guilt, by the secret determination of Heaven concerning them. Besides, God who hath ordained the end, hath also determined the means leading to it. St. Paul in his dangerous voyage, had a special revelation to assure him, that all who were with him should escape; and yet, when the seamen were getting out of the ship, he declares, that if they did not stay in it, they could not be saved. Acts xxvii. 31. God purposed to preserve them in the way whereby they were afterwards delivered.

4. We should not do evil that good may come.

If *inoculation* is in its own nature a moral evil, it certainly should be rejected, however great its advantages may seem to be. The prospect of relief from any calamity in life should not tempt us to offend God. But those who make this objection, proceed on a mistake. Their principle is true with regard to moral evil, but is not so when applied to physical. It is certainly lawful to pull down a house, to save a great number from being burnt; this is a physical evil, which can hardly take place without some degree of moral evil; and many other instances may be pointed out, where for a greater good, a lesser ill is submitted to. And is the small ill induced by *inoculation* to be compared with all those evils which are tolerated and authorized by all laws?

5. The patient may die; and then his last moments are distressed; and the future reflections of his friends are grievous.

This objection leads many to decline the practice of *inoculation*, even when they allow the theory of it to be reasonable. They hope to escape the distemper in the natural way, and they have fears of dying in this, and thus they are prevented from going into it. But they should consider what grounds they have for either the one or the other, and what is to be advanced to balance the account, by examining the different degrees of probability that attend their hopes and fears, in the use or neglect of *inoculation*. Dying is a serious thing; but if *inoculation* be a *probable* and *lawful* means of preserving life in a time of danger, it is a duty to comply with it; and what more peaceful reflection than to die in the way of duty?

6. Fear is a dangerous passion in the small-pox; but *inoculation* increases the causes of fear, by lessening our faith and trust in God.

When the small-pox is left to nature, such are its ra-

rages, that not to fear, would be to sink beneath humanity's consequences are too grievous to be treated with neglect. But experience manifests the safety that attends receiving the disease by inoculation; it is therefore to let a remedy to that full fear, which enhances the danger, when the disease is left to itself. As to faith in God, none is delicate but that which is agreeable to the S. figures, and a disregard to calamities and dangers are never the effect of that. *Inoculation* is a means of safety; and it is as rational to conclude, that our lives should be preserved without eating and drinking, as that we shall be delivered from danger without a prudent care for our own safety. We are to depend on the care of Providence only in the way of duty. To boast of courage and trust in God, while we omit the means of escaping danger which surrounds us, is not faith, but presumption.

Thus, when *inoculation* becomes a probable means by which to save life, it is a presumption, and not trust, to neglect it.

Inoculation does not exempt from future infection.

If by *inoculation*, of the small-pox, the same disease is produced, the same effect may be expected from it when artificially produced as in the natural way. It is inconceivable, that a contagious substance, the very seminal matter of the small-pox, should propagate, instead of its own, another disease. Dr. De Haene, is an acute physician, and was a violent opposer of *inoculating* the small-pox; but he never supposed that the matter of the small-pox will produce any disease but itself. Observation does determine the opinion, that the natural small-pox does not attack a second time; the same stands good in favour of the artificial disease. Add to this, numberless trials have been made without effect, to infect those in whom the small-pox had taken place by *inoculation*.

2. Other diseases are communicated with the matter of the small-pox, by *inoculating* it.

That carelessly or wilfully in the operator may in some instances give cause for this objection, is true; but, that by the matter of a varicelous pustule, any other disease hath been conveyed, is yet to be proved. As the confluent and malignant small-pox have not yet been offered to produce their own degree and mode of this disease, when infused by *inoculation*, it is scarcely conceivable that they should transmit another disease, essentially different. The venereal disease is known to be as communicable as any, yet several have been *inoculated* from patients labouring under considerable degrees of the venereal disease, and no ill consequences ever yet were known to follow, none to give the least suspicion of the kind. If the varicelous matter may convey another disease in the artificial, it may do the same in the natural way; and even then, advantage is attendant on *inoculation*, for we can choose a healthy person to take the infection from; but no instance of the kind hath ever occurred.

3. Perhaps the disease may never attack in the natural way.

Such objections should be informed, that this disclaimer cannot be given to one who never would have it; for they only who are susceptible of it can take it by *inoculation*, as is evident from numerous experiments made to verify this fact. Again, the small-pox may be said to be general; for few there are who are exempted from it, that they can hardly be considered as an exception to the general law; and it is worth while to *inoculate*, first, to ascertain the safety of the individual from this disease; and, secondly, on account of the general advantages of this practice, in case he should be susceptible of the infection. On this subject Dr. Jurin hath inserted an ingenious paper in the Philosophical Transactions in which he observes, that it is difficult to ascertain the exact number who die without having the small-pox; but that, of all the children that are born, there will some time or other die of the small-pox one in fourteen; and that of persons of all ages taken off of the small-pox, there will die thereby two in eleven.

From a table of burials it appears, that in Edinburgh and St. Cuthbert's parish, during ten years, about one-tenth of the dead were killed by the small-pox.

Farther, it cannot be known that any individual is exempted from the small-pox, his hazard of dying of that disease, being made up of the hazard of having it, and the hazard of dying of it, if he has it, will be exactly the same, viz. that of one in eight or nine (whether the proportion of mankind that escape having the small-pox be 8 out of 9). In enquiry to see how to loose for the number of people with the small-pox, in several towns, during one year, it appeared that near one in five died without having it; and that of eighty-two persons who were inoculated in these places in the same year, not one died.

1. It requires much thought to know what we should do with regard to *inoculation*.

Not to dwell on the absurdity of this objection, and of complaining that consideration is a burden, when it is necessary for the preservation of life, it may suffice to point out, that a feared writer tells us, that a prudent man foreseeth the evil, and hioeth himself; but souls pass on, and are punished.

11. It endangers others.

Since very few of mankind now escape the small-pox, it must sooner or later come to every place; therefore, if it is true in fact that a much greater number lose their lives by the natural than by the artificial infection, it is of more service to introduce the small-pox in a favourable way and season, than passively to allow them to destroy multitudes. As to spreading the disease, by *inoculating*, it is but of little consequence; for *inoculating* where the disease does not already exist, is differently circumstanced from this practice, where it already prevails in the natural way; the quantity of the communicable contagion is less, or the same extent of atmosphere is left impregnated with the infectious principles from *inoculated* patients than when it naturally prevails, or the same number of people received it in the natural way.

The most plausible objector on this account is Dr. Rast, of Lyons, in France. From his review of the bills of mortality in and about London, he observes, "that more have died by the small-pox in London since the introduction of *inoculation*, than in the same time preceding that period, in consequence of the disease there;" by being more universally extended and propagated. But to this, Dr. Leti on a noble confidence reply, "That the late increase of mortals cannot depend upon the small-pox of *inoculation*, under which, though it is a rare thing to hear of a fatal case, but rather upon the innovation introduced in the treatment of the natural small-pox of exposing the patients to the open air, and a less reserved intercourse amongst the community."

This, with the improvements in medicine in various instances, the police of the city, &c. which by preserving many lives, occasion more subjects for the small-pox; and consequently a proportional increase of deaths by this disease; many of these who are preserved by the above named improvements not being favoured with the advantages of *inoculation*. Besides the care taken in and about London to prevent inconvenience from *inoculation*.

12. It should be remembered, that the increase of the number of young persons to be educated in the schools, try, early accounts for the increase of 19 deaths in 1700, more than formerly happened."

See a Defect of *Inoculation*, in Dr. Keil's Memoirs.

13. The practice of *inoculation* comes from the devil. The best answer to this Remedy is, first, that carriers will never cease from objecting; and a tradition will be made as long as there are men of wit to devise, or of folly to invent. Secondly, that Job was afflicted by the devil with the small-pox, is not a known fact. Thirdly, that it by what is said, the principal objections are removed, it is hoped that the reasonable and the religious will be enabled to approve themselves to God in the practice of *inoculation*. See a discussion of most of the preceding objections in an excellent pamphlet, entitled, *Inoculation* impartially considered, and proved to be consistent with Reason and Revelation, by the Rev. Mr. David Some, published by Dr. Doering in 1750.

INOCULATION, advantage of. Though no disease after it is formed hinders the powers of medicine more than the small-pox, yet more may be done by one-hand to render this disease favourable than in any other we know. The artificial method of producing the small-pox hath almost stopped it of its terrors; in general, hath rendered its aspect mild, its progress uniform, and nearly without hazard to the patient.

Mr. Mudge, in his Dissertation on the inoculated Small-pox, enumerates the following sources of danger from this disease, viz. 1. The patient's constitution. 2. The propensity of the patient to be infected. 3. The manner or mode of the infection being communicated. 4. The constitution of the air at the time of infection. And, it is the advantage of *inoculation*, if prudently conducted, almost totally to exempt its subjects from the disadvantages attendant on these sources.

1. Respecting the habit of body, or state of the patient's constitution at the time of infection.

Constitutional or habitual diseases, in general, do not interfere with the course of the small-pox, whether in its natural or its artificial progress; such as venereal eruptions on the skin, strumous complaints, itch, scabby eruptions, excoriated ears, &c. The various opinion is therefore a thing, for general, and no ways affected by these taints of the juices, or what is usually called a bad habit of body; or at least so inconsiderable, as not to deprive such patients of any of the advantages of *inoculation*. But the case is much reversed with respect to some accidental diseases.

diseases. E. gr. If on the attack of the small-pox, the habit, or its attending circumstances, tend to inflammation, or on the contrary, to a putrid anæmia, the eruptive fever in these aggravated states, will load the body with various matter, or produce pulsiles of a very unfavourable kind; in either of these cases (not to enumerate more) the patient will most probably be severely affected.

But, *insulated* subjects may be infected when the constitution is in the best condition to combat with the disease; if either of these indispositions are attendant, or any other which usually endangers, they may soon be restrained or removed.

2. The different degrees of propensity in the patient at different times to be infected.

That different quantities of matter are produced in different persons in the process of the disease, we find true in fact: and there is the strongest reason to believe, that previous to infection, the quantity of the various matters, or rather that principle in the constitution, which eventually produces it, ebbs and flows, is more or less vigorous at different times in the same subject, under various combinations of circumstances. The influences are not uncommon, where the patient who hath withstood on one time all the ordinary means of infection, may, who hath indolently, but ineffectually fought it, yet at another hath had a small-pox so malignant in appearance and effect, that the whole body hath been converted into an offensive various putrescence. If the degree of propensity to receive infection was always the same, it would be inconceivable that any one could pass uninfected, when the small-pox became epidemic. From whatever causes, however, this propensity may arise, it is most reasonable to assert, that the increase or decrease of this principle takes place according to the small-pox is epidemic or not. During the continuance of any contagious epidemic disease, we always find that those constitutions which are most congenial with that character, are peculiarly obnoxious to the correspondent distemper. And we may reasonably conclude, that when the constitution of a person not passed the small-pox is most saturated with the various principle, he is then more particularly subject to infection. Again, it is not only undoubted, that the various principle subsists in the constitutions of persons not passed the small-pox, but is more than probable, that a part of this principle is produced by the eruptive fever, and the rest of the various process. Agreeably to what hath been said, we find, that during the epidemic tendency, those who have not passed the disease, are more open to contagion than in other constitutions of air, when the small-pox is not epidemic, and is consequently a rare disease. Many who have escaped infection from *insulation*, and other means of contagion, on removal into a situation where the small-pox has been epidemic, have frequently after been seized with this disorder. Events of this kind are so common, as to have given rise to the ill grounded opinion, that any change of air is hazardous to those who have not had the small-pox. If at a time when the propensity to be affected is the greatest, there should be a concurrence of those states of the constitution above noticed, how aggravated will the condition of the patient be.

Respecting the evasion of these inconveniences by *insulation*, it is to be observed, that as the propensity to the disease differs at different times in the same subject, it is reasonable to suppose that the disorder is produced by downright violence, when there subsists in the patient but little of that peculiarity of constitution, so essential to the production of the disease (and so general, when the small-pox is epidemic) or, in other words, when the body is indisposed to be poisoned. This consideration peculiar to the disease, when artificially produced, appears to be the true cause of the small quantity of pocky matter, and that general scarcity of pustules, when compared to the natural small-pox, which has ever accompanied *insulation*, and is one of the grand advantages of the discovery. Farther, as it is very reasonable to suppose, that this propensity is the greatest when there is an epidemic constitution of the air, which favours the production of the disease; and if it be as probable that the severity or mildness of the disease depends in a good degree upon the greater or lesser propensity of the subject to be infected, it will certainly be an eligible step not to bring on the disorder by *insulation*, during the continuance of an evidently prevailing tendency to the disease. Prudence in this case directs us to take advantage of the absence of such a prevailing tendency, when all the benefits of *insulation* may be secured, and not delay the operation, till such a constitution of air prevails, as at once makes the operation necessary, and deprives it of some of its advantages. To conclude, we may add to this consideration, that by the practice of exposure to

cold, the violence of the eruptive fever is so far moderated, as to prevent its forming an additional quantity of various matter, which, in a violent and unrestrained state, it would do, by assimilating the juices of the constitution into the nature of the various poison.

3. The manner or mode of the infection being communicated.

In the natural small-pox, the disease may be produced by an accidental contagion, or an epidemic influence. Dr. Mead says, that the air of this climate never produces the plague, small-pox, or measles; and Dr. Arbuthnot says, that the plague itself may be generated by some quality in the air, without any contagion. Be these opinions as they may, it is evident that contagion is sometimes to languish, that it requires the agency of other causes to give it activity, so as to produce the tribe of diseases to which it belongs, and which without this agency would never be brought forth; and though the strongest epidemic tendency may not in Europe create the small-pox, without the concurrence of contagious fomes, yet there is, by the agency of the former, such an alteration made, and propensity brought on the animal juices, as is essentially necessary to continue the existence of the disease. Various contagion produces its effects by the actual application of its poison, either externally, through the medium of the skin, or internally, to the gullet, stomach, and guts, in the act of deglutition; or bilily, to the lungs, in the act of respiration. Though there may be a possible admission of the poisonous miasmata into the constitution through the skin, from the principle of absorption, yet the poison, very seldom, if ever, exerts its influence upon the habit in this manner; possibly by a local actual application of the genus matter lodged in the clothes, or otherwise conveyed, the distemper may sometimes be produced by a kind of *insulation*, and then the disorder will probably be favourable. But when the poison, in a more diffuse state, only floats in, or impregnates the air, it seldom enters the pores of the skin, and poisons by way of absorption; for the degrees of activity in which this power is exerted, are most probably in proportion to the aids the constitution may stand in need of from it. However, it is more than probable that the ordinary mode of infection is by the lungs, which from their structure they are well calculated to receive, to entangle, and to retain. When either the lungs or the stomach are first infected by the infectious effluvia, it is most reasonable to believe, that these noble parts, together with the fauces, pharynx, wind-pipe, and gullet, will frequently labour under a greater load of pustules, than the external surface of the body; for it is observed that when the patient is infected artificially, the parts to which the poison is applied, suffer in a greater degree than the more distant; and that the circumjacent skin, to some extent, is filled with pustules. From this particular application of the morbid matter to the fauces &c. it is probable, that the large discharge of saliva, &c. arises, which characterises the conduct small-pox in adults; and as children swallow this saliva it excites a diarrhoea, which in them answers to the spitting in those more aged. When the internal parts are oppressed with pustules, there is no interval between the eruptive and the subsequent symptomatic fever; and the suffering which the patient labours under from a generally inflamed skin, heightened by the diseased condition of the nobler parts, perpetuates the first fever. This informs us that all is not so well within, as otherwise the external appearances might have induced us to believe; but that the nobler parts are rendered unfit for the purposes of life, at least are labouring and lagging behind in the process, so that they have not kept pace with the apparent state of the disease on the surface of the body; this I have supposed to be the true general cause of the secondary fever, under which the patient, if he sinks, dies peripneumonic. These consequences frequently attend the infection received in the natural way, and if, superadded to these, the unhappy situation of those described under the first and second sources of danger attends the patient, the disorder will be proportionally aggravated, and the chance of life lessened.

But here again *insulation* relieves: for by this mode the virus is applied to the external surface of the body, so that the whole constitution (excepting the part immediately surrounding the wound) being affected uniformly, the process of the disease is regularly carried on, and the nobler parts not being particularly affected by a partial application of the various fomes to their surface, have no difficulty to proclaim by a secondary fever, which is therefore scarcely ever seen in *insulated* patients.

4. The constitution of the air at the time of infection. A powerful source of difficulty and danger in the habitual small-pox, is the malignant influence of the air at some seasons, and particularly if it happens at the time of receiving the infection. If this concurs with one or

more of the other sources, how dreadful the devastation. Whether this constitution of the air produces its deleterious effects, by heightening the natural malignity of the infecting poison, or acts on the constitution itself, for as to render the effects of contagion more peculiarly fatal, the consequence of this state of the air is the same. The general character of a morbid state of the air, are the inflammatory and putrid; and it is uniformly observed, that whenever a person is attacked with a fever, under either of these prevailing dispositions, it never fails to impregnate its character upon the disease.

But here also *insalutatio* affords the most benign influence. The judicious practitioner does not expose his patient to the pernicious effects of an air that can stamp its baneful character on the small-pox; but chooses the season best calculated for the safety and welfare of his patient; and hence we rarely see the influence of this evil source attendant on the artificial disease.

Having seen, that from the influence of one or more of these four sources of difficulty and danger, and that from their union will result a natural small-pox, complicated with horrors not less to be dreaded than the plague, how inestimable must appear that favor of Providence, by which we are freed from the formidable attendants of this disease, viz. *insalutatio*, by which the disorder is rendered mild, and in general less hazardous than a common cold.

From attention to the above sources of ill in the natural small-pox, we are led to see, with sufficient satisfaction, the many influences of relief and security which generally we avail ourselves of by *insalutatio*, a part of which we have seen, and a few others follow.

As already observed, it saves the lives of most who are its subjects.

From a general calculation it appears, that in the hospitals for small-pox and *insalutatio*, 72 die out of 100 patients having the distemper in the natural way, and only one out of this number, when *insalutatio*.

It lessens the affliction from both the degree, and the number of its symptoms, even when it proves fatal.

It lessens the number of pustules; and by moderating the virulence of the disease, the marks on the face are not so deep.

It is extremely rare that the secondary fever attends it; a symptom productive of much suffering, if the patient is happy enough to escape with life.

It produces the disease under the fewest disadvantages, and favours with foresight to prevent many ills, not to be guarded against in the natural small-pox.

Instead of communicating other disorders with it, many disorders subsequent to the natural, are very rarely observed after the artificial small-pox.

It effectually removes all just grounds of fear; a passion very injurious in this disease.

Soldiers, sailors, and all who would appear abroad, or, in public offices, are freed from every anxiety and hazard, attendant on the natural small-pox.

Servants, women with children at their breasts, pregnant women, magistrates, physicians, &c. are all freed from the most distressing embarrassment, by conformity to *insalutatio*. See *Small-Pox*.

INOCULATION, hospital for. See **HOSPITAL**.

INORDINATE proportion, is where three magnitudes being in one rank, and three others proportional to them in number, you compare them in a different order.

E. g. If there be in one rank these three numbers, 2, 3, 9; and in another rank, these other three, 8, 24, 36, which are proportional to the precedent, in a different order; so that 2 be to 3 as 24 to 36, and 3 to 9 as 8 to 24; then calling away the mean terms in each rank, you conclude the first 2 in the first rank to be to the last, 9; as 8, the first of the other rank, to the last, 36.

INOSARCION, in *Natural History*, a name given by the old Greek and Roman authors to a peculiar species of emerald, called also by some the Chalcidonian emerald. The great distinction of this from all the other kinds of this gem, was its not being of the pure, clear, and unvarying colours of the others, but having thick veins in it, which gave peculiar refractions and reflections to the light; and though the stone was in itself wholly green, yet when viewed in side lights, these veins gave all those changeable colours that ornament the feathers of a peacock's tail, or the neck of a pigeon.

INOSCUATION. See **ANATOMASIS**, and **ARTERY**. **IN PACE**, a Latin term, used among monks, to signify a prison, where such of them are shut up as have committed any grievous fault.

Formerly, there used to be a great deal of ceremony at the putting a religious in *pace*; but now it is not much regarded. Such as are shut up in perpetual imprisonment, are also said to be in *pace*.

Sometimes, also, the words *requiescat in pace* are used by

way of allusion to a custom in the Romish church, of praying that the soul of the deceased may rest in peace.

The same words are also frequently seen at the bottom of epigraphs, in lieu of those used by the ancient Romans, *S. T. T. L. i. e. sit tibi terra levis*, Light be the earth to thee, or, *Sit humus ciniri non curiosa tui*.

IN PALE. See **PALE**.

INPROMPTU, or **IMPROMPTU**, a Latin word frequently used among the French, and sometimes in English, to signify a piece made off-hand, or extempore, without any previous meditation, by the mere force and vivacity of imagination.

INQUEST, or **ENQUEST.** See **ENQUEST**, **ARREST**, and **JURY**.

INQUIRENDO, an authority given a person or persons, to inquire into something for the king's advantage.

INQUIRENDO istius. See **INDICTA**.

Ad INQUIRENDEM. See **Ad INQUIRENDEM**.

Illius INQUIRENDEM. See **MILIUS**, &c.

INQUISITION, in the *Civil* and *Canon Law*, a manner of proceeding for the discovery of some crime by the office of the judge, in the way of search or examination. **INQUISITION** is also used, in *Common Law*, for a like process in the king's behalf, for discovery of lands, profits, and the like.

In which sense it is also confounded with **OFFICE**.

INQUISITION, or the *Holy Office*, denotes an ecclesiastical jurisdiction established in Spain, Portugal, Italy, &c. for the trial and examination of such persons as are suspected to entertain any religious opinions contrary to those professed in the church of Rome.

It is called *inquisitio*, because the judges by their office take cognizance of crimes on common report, without any legal evidence, except what they themselves are able to explore.

Some people fancy, they see the original of the *inquisition*, in a constitution made by pope Lucius, at the council of Verona, in 1154, where he orders the bishops to get information, either by themselves, or by their commissaries, of all such persons as were suspected of heresy; and distinguishes the several degrees of suspected, convicted, penitent, relapsed, &c. However this be, it is generally allowed, that Pope Innocent III. laid the first foundation of the *Holy Office*; and that the *Vandouls*, and *Albigenses*, were the first objects of it. That pontiff, at the beginning of the thirteenth century, sent Raimond, a Cistercian monk, and Pierre de Castellau, archbishop of Maguelonne, to the country of Thoulouse, or *bonne Gaul*, in order to blow up a spirit of zeal and perfection amongst the prelates and princes. These missionaries were soon followed by others, among whom was the famous Spaniard, Dominic, founder of the order of Preachers, who, returning from Rome in the year 1206, fell in with these delegates, embarked in their cause, and laboured, both by his exhortations and conduct, in the extirpation of heresy. These spiritual champions were to give an account to the pope of the number of heretics in those parts, and of the behaviour of the princes and persons in authority to them; and thence they acquired the name of *inquisitors*; but these original *inquisitors* had not any court, or any authority; they were only a kind of spiritual spies, who were to make report of their discoveries to the pope, and to excite the catholic princes and people to extirpate heretics.

It has been generally said, that the tribunal of the *inquisition* was the invention of St. Dominic, and first erected by him in the city of Thoulouse; that, consequently, he was the first inquisitor; and that, although the year of its institution is uncertain, it was undoubtedly confirmed in a solemn manner by Innocent III. in the council of the Lateran, in the year 1215. See *Limbotch's Hist. of the Inquisition*, by Chandler, book i. chap. 10.

This account is contested by Mosheim, who maintains, that St. Dominic was not appointed by the Roman pontiff to proceed judicially against heretics, and such as were suspected of heresy, to pronounce sentence according to their respective cases, and to deliver over to the secular arm such as persisted obstinately in their errors, and therefore, in this sense, was no inquisitor; though, according to the original meaning of the term, he was invested with the commission and authority of the Roman pontiff to extirpate heresy, and oppose its abettors, but without any judicial power; nay, it is farther urged, that the court of *inquisition* was not erected during the life of St. Dominic. The horrid war, which was excited by Innocent III. against the *Albigenses* in Narbonne Gaul, and which was carried on by the cross-bearers with the utmost cruelty from the year 1209 to 1220, when a treaty of peace took place between Raymond VIII. earl of Thoulouse, and Lewis VIII. king of France, which gave a mortal blow to the cause of heresy, prepared the way for the full establishment of the *inquisition*. Inqui-

factors of the first kind had, in the course of this time, been placed in almost every city, whose inhabitants had the misfortune to be suspected of heresy, notwithstanding the reluctance which the people manifested to this new institution, and the violence with which they frequently expelled and sometimes massacred their bloody officers of the popish hierarchy. At length, the council held at Thoulouse, in the year 1233, by Romanus, cardinal of St. Angelo, and pope's legate, went still farther, and erected in every city a council of inquisitors, consisting of one priest, and three laymen. This institution was, however, superseded in the year 1233, by Gregory IX. who entrusted the Dominicans, or Preaching Friars, with the important commission of discovering and bringing to judgment the heretics that were lurking in France; and in a formal epistle discharged the bishops of this painful office. Immediately after this, the bishop of Tournay, who was the pope's legate in France, began to execute this new resolution, by appointing Pierre Gellan and Guillaume Arnaut, inquisitors of heretical pravity at Thoulouse; and afterwards proceeded in every city, where the Dominicans had a convent, to constitute officers of the same kind, chosen from among the monks of that order. From this period we are to date the commencement of the dreadful tribunal of the *inquisition*, which in this and the following ages subjected such a prodigious multitude of heretics, part of whom were converted to the church by terror, and the rest committed to the flames without mercy. For the Dominicans erected first at Thoulouse, and afterwards at Carcassonne, and other places, a tremendous court, before which were summoned not only heretics, and persons suspected of heresy, but likewise all who were accused of magic, sorcery, Judaism, witchcraft, and other crimes of that kind. This tribunal, in process of time, was erected in the other countries of Europe, though not every where with the same success. The method of proceeding in this court of *inquisition* was at first simple, and almost in every respect similar to that which was observed in the ordinary courts of justice. But the Dominicans modelled it after that of the tribunal, called in the Roman church the tribunal of peace; and hence arose that strange system of inquisitorial law, which, in many respects, is so contrary to the common feelings of humanity, and the plain dictates of equity and justice. And that nothing might be wanting to render the spiritual court formidable and tremendous, the Roman pontiffs, persuaded the European princes, particularly the emperor Frederic II. and Lewis IX. king of France, not only to enact the most barbarous laws against heretics, and to commit to the flames those who were pronounced such by the inquisitors, but also to maintain the inquisitors in their office, and grant them their protection in the most open and solemn manner. The edicts issued to this purpose by Frederic II. are well known; edicts every way proper to excite horror, and which rendered the most illustrious piety and virtue incapable of saving from the most cruel death such as had the misfortune to be disagreeable to the inquisitors. The laws of Frederic, in relation to the inquisitors, may be seen in Limborch's History of the *Inquisition*, book i. chap. 12.

The edict of St. Lewis, in favour of these ghostly judges, issued out in the year 1259, is generally known under the title of *Copisatus*.

After the death of Frederic, who had long before repented the power he had given the churchmen, as having seen some of the fruits of it, pope Innocent IV. erected a perpetual tribunal of inquisitors, and deprived the bishops and secular judges of the little power the emperor Frederic had left them. And this jurisdiction, which depended immediately upon himself, he made care to introduce into most of the states of Europe. In 1261 it was established in Italy; in 1265 Alexander IV. appointed inquisitors in France, at the request of St. Lewis. But the inquisitors were so fiery hot, and made such horrible butchery among the reputed heretics, that they raised an universal detestation even in some catholic countries themselves. Hence it was that their reign proved very short both in France and Germany; though they were occasionally exerting themselves; and their power was established in many parts of France and Germany about the time of the reformation by Luther; but afterwards gradually declined. Nor was even Spain entirely subject to them till the time of Ferdinand and Isabella, when their power was increased, under pretence of clearing the country of Judaism and Mahometanism.

The *inquisition* was first introduced into Spain in the year 1478; but the first inquisitor-general, and the supreme council of the *inquisition*, were not fixed till the year 1483. This tribunal is arisen to such a height in Spain, that the king of Castile before his coronation subjects himself and all his dominions, by a special oath, to the most holy

tribunal of the *inquisition*. It is under the direction of an inquisitor-general, appointed by the king, and confirmed by the pope; and this *inquisition* has power to name particular inquisitors in every place where there is any tribunal of the *inquisition*.

The *inquisition* was established in Portugal, at the pressing solicitation of king John III. about the year 1536; and both the Spaniards and Portuguese have established it in their territories in the western continent.

The power of the *inquisition* is very much limited in some countries, particularly at Venice, where it is introduced about the year 1289, and where it is received under such modifications, as prove a great check on its authority; the office consisting of secular and ecclesiastical persons, though the latter have been long endeavouring to bring it into their own hands, but could never prevail with the Venetian senate to agree to it. Indeed at Venice it seems rather a political than a religious contrivance; and serves rather for the security of the state, than that of the church. There are appeals from the subaltern *inquisition* in Italy, to the congregation of the holy office residing at Rome.

This *congregation* was first formed by Paul III. in 1542, but finally established by Sixtus V. in 1588. The members of it, called *supreme inquisitors*, assemble thrice in the week, and every Thursday in the presence of the pope, who presides in it.

The officers or ministers of the *inquisition* are the inquisitors, who derive their power from the pope, either by word of mouth, or by his apostolic letters, and can be removed only by him, or by authority conferred by him on those cardinals who are the inquisitors general; vicars general, who manage the affairs of the *inquisition*, during the absence of the inquisitors; assessors and counsellors, who give their advice in points of theology and law; the promoter fiscal, whose office it is to examine the depositions of the witnesses, to give information of criminals to the inquisitors, and to demand their apprehension and imprisonment; and, finally, when apprehended and admonished, to accuse them; notaries or registrars, who write down the injunctions, accusations, and all the pleadings of the causes; the judge and receiver of the confiscated effects; the executor and officials, who apprehend and keep in custody criminals; the attendants or *coadjutors*; the *cross-heretics*; and the visitors, who visit all the provinces of the inquisitors, and report to the inquisitor-general and council whatever was proper to be accommodated. The civil magistrate is entirely excluded from the cognizance of heresy; but the inquisitors require their assistance for the punishment of heretics, in consequence of the sentence which they pronounce; and they are severely threatened with the most grievous punishments, if they neglect their duty. The punishments inflicted by the *inquisition* on heretics are ecclesiastical and civil: the ecclesiastical or canonical are *excommunication*, deprivation of ecclesiastical burial, dignities, benefices, and offices. The civil are confiscation of goods, which is inflicted on all who are convicted of heresy, or confess, whether they repent or persist in their heresy, because they are declared to incur the punishment, *ipso facto*, as soon as they fall into heresy; disinheritance the children, inasmuch that though they are catholics, they can never inherit the estates of their fathers who died in heresy; infamy, which excludes from all public offices, from bearing witness, making wills, &c. loss of all dominion, natural or civil, as power of parents over children, masters over servants, magistrates and princes over subjects, &c. and the deprivation of all property in every thing they have; imprisonment; ban, which is a kind of sentence of excommunication, by which any person is cut out of the commonwealth, so that he cannot enjoy the public protection, or discharge any public offices, or receive any benefit of law; diffamation, which declares heretics to be enemies of their country and of the empire, so that any person, by his own private authority, may seize, plunder, and kill him, as an enemy and robber, even though he be a clergyman; nor is it lawful for any one to undertake their defence when apprehended; and those advocates who favour and plead for them, are pronounced infamous, and suspended from their office; and finally death, which is that of being burnt alive, in some cases heightened by being gagged with an iron instrument, so that in the midst of their torments they can ever only utter an inarticulate sound.

It is the constant practice of the *inquisition* to affect, in all their procedures, to inspire as much terror and amazement as possible; every thing is done with the profoundest silence and secrecy, and with the greatest rigour, and pretended impartiality. When a person is seized, all the world abandons him; not the nearest friend dares to speak a word in his defence; that alone would be enough to render them suspected of heresy, and would bring them

them within the claws of the *inquisition*; nay, the nearest relations are bribed and constrained to accuse one another. The criminals are seized, examined, tried, tortured, and, unless they recant, are even condemned and executed, without ever seeing or knowing their accusers; whenever the revengeful have a fair occasion of wreaking their malice on their enemies. By the forms of the *inquisition*, a person defamed only for heresy is obliged to make canonical purgation, i. e. to purge himself with seven, more or less, comparators; so that if he fails in one, two, or three, he is accounted guilty; besides, every one, though excluded by other counts, is admitted as a witness, a mortal enemy only excepted. The names of the witnesses are not shown to the prisoner; nor is any circumstance discovered, by which he can obtain the knowledge of them. If two unexceptionable witnesses testify of sufficient facts, yes, sometimes if there be only one, or a mere report, it is thought sufficient for ordering the torture; the evidence of two unexceptionable witnesses, who agree, is sufficient for the conviction and condemnation of any person. Those that are informed against are constrained to become their own accusers; and various arts are used to extort confession from them. The advocate allowed them is under the direction of the *inquisitor*, and employed chiefly in order to betray them; moreover, when the crimes cannot be proved against them, they are only absolved from prosecution, but their crimes and names are recorded against them. The use of torture for discovering secret crimes lying concealed in the mind, is a flagrant instance of injustice; and persons are put to the torture upon half proof of the crime, i. e. flattery, defamation, one witness of his own knowledge, or when the tokens are vehement or violent. These tortures are used under a pretence of discovering the truth, and they are varied and continued with the most wanton cruelty. After these, and many other shocking processes, when the *inquisition* has done with the criminals, and condemned them to death, they are turned over to the secular arm, with much prayer, and pious intreaty, that their lives may not be touched. Time is no manner of security in point of heresy; nor does the grave itself shelter the accused from the pursuits of the *inquisition*; even the deceased have their trials, and they proceed in all their form and solemnity against the dead carcasses. The executions are always deferred till the number of the condemned is very great, that the multitude of sufferers may strike the deeper horror, and make the scene more terrible and shocking. See *ACT of Faith*.

The *inquisition* is very severe in the Indies. It is true, there must there be the oath of seven witnesses to condemn a man; but the deposition of slaves or children are taken. The person is tortured till he condemns himself; for his accusers are never brought to confront him. Persons are accused for the blindest expression against the church; or even for a disrespectful word of the *inquisitor*.

The standard of the *inquisition* in Spain is a piece of red damask, on which is painted a cross, with an olive-branch on one side, and a sword on the other; with these words of the psalm, *Exurge, Domine, et iudica causam meam*.

The standard of the *inquisition* in Portugal hath their supposed founder, Dominic's picture on one side, and on the other like the cross, between an olive-tree and a sword, with this motto, *Justitia et misericordia*.

See on the subject of this article Limborch's Hist. of the *Inquisition*, by Chandler, p. 100. Mosheim's Eccl. Hist. vol. iii. p. 113, &c. &c.

INQUISITORS, in *Law*, are sheriffs, coroners *super vium corporis*, or the like, who have authority to enquire into certain crimes, &c.

IN QVO, *Medicus in quo*. See **MEDICUM**.

INROLLMENT, in *Law*, the registering, recording, or entering of any lawful act, or instrument, in the records of chancery; as a recognizance acknowledged, or a statute, or a line levied.

Judgments are also made in the rolls of the exchequer, king's bench, and common pleas, in the hallings at Guildhall, London; and by the clerk of the peace in any county. See **REGISTER**.

INROLLMENTS, *clerk of the*. See **CLERK**.

INSAG, in *Natural History*, a name given by the people of the Philippine islands to one of the several species of parrots, common in their woods. The *insag* is a very beautiful bird; its body is of a very bright green, and its head of a fine florid red.

INSANUM parlamentum. See **PARLIAMENTUM**.

IN-SCHI, or **INACHI** *tea*, in the *Materia Medica*, a name given by some authors to the common ginger.

INSCONCED, in the *Military Art*, denotes that part of an army that have fortified themselves with a *saucer*, or small fort, in order to defend some pass, &c. See **SCORCE**.

INSCRIBED, in *Geometry*.—A figure is said to be *inscribed* in another, when all the angles of the figure *inscribed* touch either the angles, sides, or planes of the other.

INSCRIBED Hyperbola, is such an one as lies entirely within the angle of its asymptotes; as the conical hyperbola called *See HYPERBOLA and CONIC SECTIONS*.

INSCRIPTION, a tale, or writing, added to any thing, to give some farther knowledge thereof; or to transmit some important truth to posterity.

Antiquaries are very curious in examining ancient *inscriptions* found on stones, and other monuments of antiquity. Santhorathon, contemporary, as it is said, with Gideon, drew most of the memoirs whereto his history is composed, from *inscriptions* which he found in temples, and on columns, both among the Heathens, and the Hebrews.

It appears, indeed, that the ancients engraved upon pillars the principles of science, as well as the history of the world. These monuments, by Herodotus flow, that this was the first way of instructing a people, and of transmitting histories, and sciences, to posterity. This is confirmed by Pline in his *Hippias*, wherein he says, that Pistratus engraved, on stone pillars, precepts useful for husbandmen. Pline assures us, that the first public monuments were made of plates of lead; and that the treaties of confederacy concluded between the Romans and the Jews, were written upon plates of brass; that, says he, the Jews might have something to put them in mind of the peace and confederacy concluded with the Romans. The Greeks and Romans were great dealers in *inscriptions*, and were extremely fond of being mentioned in them; and hence it is, that we find so many in those countries of ancient learning, that large volumes have been composed; as the collection of Gruter, &c. Since Gruter's collection, Th. Reinellus has compiled another huge volume of *inscriptions*. M. Fabrety published another volume at Rome in 1699, wherein he has corrected abundance of errors which had crept Gruter, Reinellus, and other antiquaries, &c. and added a great number of *inscriptions* omitted by them—Since all these, Grutius has published a complete collection of *inscriptions*, in three volumes in folio. In France is an *ACADEMY of inscriptions* and medals, the members of which are to meet twice a week, and employ themselves in the annotation of medals and ancient monuments, and of the parts of Greek and Roman literature; and to compile a history of the kings of France from medals. See *Academy of the Academy* at the time of its institution, or rather rather later, in the beginning of this century; but as they are not now wholly employed about medals and *inscriptions*, they have changed their name for one of a greater latitude, and are called the *Academy des Belles Lettres*.

INSCRIPTIONS, *Nites*, or *Abbreviations*, used in. See **CHARACTER**.

INSCRIPTIBLE, *Unsearchable*, in *Theology*, is usually understood of the secrets of Providence, and the judgments of God, which cannot be found out, or into which human reason cannot penetrate.

INSECTS, **INSECTA**, (this word is originally Latin, formed of *in*, and *sect*, *I cut*; the reason of which is, that in some of this tribe, as ants, the body seems to be cut, or divided into two, or because the bodies of many, as worms, caterpillars, &c. are composed of divers circles, or rings, which form a sort of inclosure), in *Natural History*, a smaller sort of animals, commonly supposed to be exanguinous; and distinguished by certain incisions, cuttings, or indentings, in their bodies.

Their characters are, that their body is covered with a sort of bony substance instead of skin, and their heads are furnished with antennae, called horns.

All insects have six or more feet, which are denominated from the various motions they produce, *crawling*, or *running*, *slithering*, or *leaping*, the thighs being remarkably large, *snoutless*, or *feemless*, which are flat and edged, with hairs; the *mund* are such feet as have no claws; the *forefoot* are enlarged towards their extremities, and each of them is furnished with two lesser claws, acting like a thumb and finger. They respire through pores placed on the sides of their bodies, called *spiracula*: the head has no brain, and is furnished neither with ears nor nostrils. Most insects have two eyes, but some have more, without eye-brows. The antennae are generally two, placed in the fore part of the head, and distinguished from the tentacula of worms, in being crustaceous: they are of various forms, and serve to distinguish the different kinds of *insects*: the principal distinctions are the following; viz. the *formicae*, which grow gradually taper towards the extremity, the *viscerum*, which are of the same thickness throughout; the *musiformes*, which are filiform, consisting of a series of round knobs; the *clavatae*, which gradually increase in size towards the extremity; the *capitatae*, which are clavated with the extremity roundly in the *figura*, which

are capitated, with the small head divided longitudinally into three or four parts or laminae: the *perfoliata*, which are capitated with the small head horizontally divided; the *pellucata*, so called from their similitude to a comb or feather; *aristata*, which have a lateral hair, that is either naked or furnished with lesser hairs; *breviscapa*, *longicauda*, and *medusaria*, which are respectively shorter than the body, longer, and of the same length with it. Besides the antennae, there are the *palmi* or *feelers*, resembling filiform, articulated, moveable antennae, but sufficiently distinguished from antennae in being naked, short, and always at the mouth: they are commonly four in number, sometimes six. The mouth is generally placed in the anterior part of the head, sometimes under the breast, and sometimes drawn out to a rigid point called the *rostrum* or *proboscis*; the maxillae or jaws are two, sometimes four or more, placed horizontally; and the inner edge in some *insects* is inflexed or furnished with little teeth. The oesophagus is in some *insects* taper and spiral, in others belly, resembling a proboscis, and tubular, as in the fly. The *sternum* or *crowns* are three smooth hemispheric dots, placed generally on the top of the head. The trunk is situated between the head and abdomen, and comprehends the *thorax*, which is the back part of the breast, being called denuded when its sides are armed with points; *spinose*, when its sides are furnished with them; and *margined*, when its margin is laterally dilated: the *scutellum* or *elctureon*, which is the posterior part of the thorax, often triangular and divided from the thorax by an intervening suture; and the *sternum*, which is situated on the inferior part of the thorax, sometimes pointed behind, and sometimes bifid. The abdomen of *insects* is the posterior part of their body, composed of a number of annular segments, which serve occasionally to lengthen or shorten it, and to contain the organs of excretion, &c. The spiracles are small holes placed singly on each side of every segment of the abdomen through which the *insect* breathes; and if oil be applied so as to stop them up, it proves fatal to most of them. The anus is the posterior part of the abdomen, perforated for the evacuation of the excrement and frequently containing the organs of generation. The wings of *insects*, which are commonly four, and sometimes two, are membranous and almost always undivided; and they are called *plexistylis*, when they are folded at the time the *insect* is at rest; *plane*, when they are incapable of being folded; *erata*, which have their superior surfaces brought into contact when the *insect* is at rest; *patentes*, which remains horizontally extended; *incumbentes*, when they cover horizontally the superior part of the abdomen; *deflexae*, which are incumbent, but the outer edges declining towards the sides; *recurvae*, which are deflex, with the edge of the inferior wing projecting from below the anterior part of the superior ones; *dentata*, which have the edge serrated or folioid; *caudata*, in which one or more projections in the hinder wings are extended into processes; and *reticulata*, when the vessels of the wings put on the appearance of network. The colours of *insects* bear different names according to their shape; thus there are *puncta* or dots, *maculae* or spots, *fuscae* or bands, which frequently run across and sometimes surround the edge of the wings; *strigae* or streaks, which are very slender fasciae; and *lineae* or lines, which are longitudinally extended. The *ocelli* is a round spot, containing a lesser spot of a different colour in its centre: the *stigmata* are the spots or anastomoses in the middle of the wing near the anterior margin; and the single or double kidney-shaped spot, situated in the same part of the anterior wings, is also distinguished by the name of stigma. The *nyra* are the upper wings, which are of a hard substance, in some degree resembling leather, and in most *insects* of a very hard texture, but in others flexible: their upper surface is generally convex, their lower one concave; they are extended when the *insect* flies, and shut when it rests, closing together and forming a longitudinal suture down the middle of the back. They are of various shapes, and called accordingly *abbreviata*, when shorter than the abdomen; *truncata*, when they also terminate in a transverse line; *sessigata*, when in the same circumstance they are of equal length with the abdomen or longer; *seriata*, when the exterior margin towards the apex is notched or serrated; *spinosa*, when their surface is covered with sharp points or prickles; *foveata*, when their surface is so uneven as to grate against the fingers; *striata*, when marked with slender longitudinal furrows; *perciata*, when they have elevated longitudinal sulci or ridges; and *fuscata*, when these ridges are concave. When the superior wings are of a middle substance between leather and membrane they are called *hemiptera*. The *halteres* or pollers are little heads placed on a stalk or peduncle, most frequently under a little arched scale.

and appearing to be nothing more than the rudiments of the hinder wings. The tail in most *insects* is simple, capable of being extended, and again drawn back at pleasure; however, in others it is elongated or lengthened out; brittle-shaped or taper; *trijugata*, composed of three bristles; *forcata*, or forked; *serpata*, resembling a foreceps; *filifera*, resembling a leaf; *telifera*, when armed with a dart or sting. The *oculus* is an instrument with which *insects* wound, and at the same time insill a poison. The same difference of sex exists in *insects* as in other animals, and they appear more disposed to increase their species: many of them, when become perfect, seeming to be created for no other purpose but to propagate their species. The difference of sex is with difficulty distinguished in many *insects*; in some, however, the difference is so great, that the male and female may be mistaken for *insects* of different species. The colour is different in some, and in others the male has wings and the female has none. Besides the sexes of male and female, there is a third distinction in some *insects* called *unsex*, which have not the distinguishing parts of either sex. No hermaphrodites have as yet been discovered among *insects*: there is something very singular, however, in the propagation of the spiders: a female *ARANEUS*, once impregnated, can produce young, which will continue to produce others without any fresh impregnation, even to the fifth progeny; afterwards a new impregnation must take place. The male *insects* are always smaller than the female. See LINNÆI Systema Naturae, tom. i. pars ii. p. 533, &c. and Fundamenta Entomologiae apud LINNÆI Ammunicatae Academicæ, vol. vii.

Dr. Hill in his history of animals subdivides *insects* into three general series, each whereof comprehends under it several classes, and those again many distinct genera.

The first series of *insects* is called *ARTERIA*; because under it are comprehended all *insects* of what kind soever, having no wings.

Of this series there are two classes, the *ANARTHRA* and *PODARIA*.

The second series of *insects* is called *PTERARIA*, as comprehending all the winged kinds.

Of this series there are likewise two orders or subdivisions: 1. The *pteraria diptera*, or *insects* with two wings.

2. The *pteraria tetraptera*, or those with four wings.

The third and last series of *insects* is called *GYMNARTHRIA*, and comprehends all those *insects* which have soft and naked bodies, furnished with limbs.

LINNÆUS distributes *insects*, the fifth class of animals, into seven orders, distinguished by their wings, viz. *coleoptera*, *hemiptera*, *lipidoptera*, *neuroptera*, *hymenoptera*, *diptera* and *aptera*, including 86 genera, and 2080 species. *Insects*, according to Mr. Ray, in his Methodus Insectorum, are either, first, *gastropodæ*, such as do not change their form; or, secondly, *metamorphosæ*, such as do really change their form.

INSECTS which do not change their form, are either 1. *Aroæa*, without feet; or, 2. *Palata*, with feet; and of these there are some kinds that cast their skins, and others that do not.

INSECTS without feet are either *terrestrial*, i. e. land-*insects*, or *aquatic*.

INSECTS, *terrestrial*, are either, first, such as are produced on the land: as the lumbrical termites, which are either of the larger sort, and called *draw-worms*; or of a smaller size; and these are some red, and others green, with yellow tails, which last are commonly called *tail-tails*.

Or, secondly, such as are found in the bowels of animals.

To the genus of *terrestrial insects*, many natural historians also refer snails, whether with or without shells.

INSECTS, *aquatic*, without feet, not changing their form, are either, first, of the greater sort, which have a peculiar way of moving, by first fixing their head to the ground, and then drawing up the tail towards it, &c. of these, some are *teretes*, round and smooth; or, secondly, of the *lesser sort*, which have a different way of crawling, or moving from the former.

There is an *insect* of a very peculiarly amphibious kind, which Mr. Reaumur has accurately described in the Memoirs of the Paris Academy. Many animals are aquatic for a part of their lives, and pass the rest on dry land; but this singular creature always continues to have its head and tail both in the water, and the intermediate part of its body out.

To conceive the manner in which this is effected, we must consider its figure: it is composed, like many other, of these small animals, of several rings or joints; it has eleven of these between its head and its tail; they are all roundish, and very well resemble a string of beads.

The creature is almost always in a bending figure representing a syphon: its head and tail are always placed near one and another, while the body is elevated and forms an arch above them, the head, the

tail, and the ring joining to the tail, are the parts constantly kept in the water; and the nine other rings, or at least seven of them, lie upon dry land. The constant habitation of the animal is at the edges of standing waters. It constantly draws back if more of the body is wetted, and plunges in deeper if less than the allotted portion is so. The animal is not more than two thirds of an inch long.

Its manner of moving is very particular; for neither the head nor the tail form concerned in it, but the highest part or back ring of the body, which in its crooked shape makes the summit of the arch, is what moves first, and draws all the other parts to follow it, the creature continuing in its bent posture while it moves. It does not move by vermicular progression, as some animals do, but has regular feet. These indeed are so small as not to be distinguishable without the assistance of glasses; but when seen, they are found to be one of the greatest singularities of the animal. See farther, *Mem. Acad. Par. 1714*.

INSECTS are changing form, and having feet, are either, first, *hexapoda*, with six feet. Secondly, *schapoda*, with eight feet. Thirdly, *decapoda*, with fourteen feet. Or, fourthly, *poly-poda*, with more numerous feet. Those that have but six feet are either *terrestrial* or *aquatic*.

INSECTS which undergo a change of their form are called *metamorphoses*, though improperly; since, as Swammerdam shews, there is no real transformation, but only an explication of the parts of the animal, latent before in miniature, like the plant in the seed, and an increase of all the parts by proper degrees. In these the first species of transformation, or change, is instantaneous, there being no sensible rest, or stop, between the old and the new form. The *insects* of this order do not lose their motion at the time they shift the pellicula, at least not to appearance.—This is when the vermicular, leaving the former shape of the nymph, with which it appeared in the egg, and subsisted without food, now beginning to feed, has its members, or parts, visibly increased, and stretched out, and takes the form of a new nymph, which is not without motion; and from thence becomes a flying *insect*.

The second species of transformation includes such *insects* as undergo a double metamorphosis, or change of shape. 1. Into a *larva*, or something analogous to it. 2. Into a flying *insect*.

These kinds of *insects*, a while before they change, lie quite still, without feeding, or changing place: and, in respect of their wings, are, first, *macroptera*, or virginipennis, as the *farfallæ*; beetles. Secondly, *microptera*, whose wings are open and expanded; and the wings of these are either farinaceous, as in the *papiæ*, &c. or membranous, as in the *osæ*, *mosæ*, &c. and these are either *diptera*, with two wings, or *triptera*, with four wings.

The third species of transformation is a simple change from a vermicular to a flying *insect*, but with a sensible *trivex*, rest or stop, between one form and the other. This change Swammerdam thus describes: “The vermicle excluded from the egg gets nourishment by little and little from without, and under that first skin, or covering, has its membranes increased by degrees: not slipping it, or putting it off, as other vermicles do when they change into nymphs, but assuming the figure of a nymph in it: for a time it is quite motionless, till the superfluous moisture is evaporated; and then in a few days, it recovers its motion again, and calling off the skin, which is, as it were, double, it becomes a fly.” See *Transformation of INSECTS* below.

INSECTS, rest of. See *EYES of Flies*.

INSECTS, generation of. The world is now generally convinced, that *insects* are not bred of corruption, but *ex ovo*; though the contrary was believed by the ancients, because of the vast numbers that were sometimes hatched, as it were, at once, and because they could not discern the particular manner of their propagation. See *GENERATION*.

Malpighi, Swammerdam, and Reaumur, have abundantly disproved the doctrine of equivocal generation, as well as the chimerical transformation of the caterpillar into the butterfly, and other like metamorphoses; and have shewn, that all the members of the butterfly were originally included under the skin or nymph of the caterpillar, as the parts of the plant are in the seed.

Insects take particular care to deposit their eggs, or seed, in such places where they may have a sufficient incubation, and where the young, when hatched, may have the benefit of proper food till they become able to shift for themselves. Those whose food is in the water, lay their eggs in the water; those to whom flesh is a proper food,

in flesh; and those to whom the fruits or leaves of vegetables are food, are accordingly deposited, some in this fruit, some in that tree, and some in one plant, and some in another; but constantly the same kind in the same tree, or plant. As for others, that require a more constant and greater degree of warmth, they are provided by the parent animal with some place in or about the body of other animals; some in the feathers of birds, some in the hair of beasts, some in the scales of fishes, some in the nose, some in the flesh, nay, some in the bowels and inward recesses of man, and other creatures. And as for others, to whom none of these methods are proper, the parents make them self by perforation in the earth, in woods, in combs, and the like; carrying in and sealing up provisions that serve both for the production of their young, and for their food, when produced.

In flies, butterflies, &c. it is observed, there is a kind of gluten, by which the female fastens her eggs to the bearing body of trees, &c. so that the rains cannot wash them off. These eggs will not be hurt by the greatest frost.

Insects, De la Generation de Vers dans le Corps de l'Homme, takes notice, that the ancients were mistaken in denying that *insects* did breathe, on the account of their wanting lungs; for modern observations convince us that *insects* have a greater number of lungs than other animals.

The ancients thought, also, that *insects* had no blood, because many of them had no red liquor like our blood; but it is not the colour, but the use of that liquor, that is to be regarded.

They believed, also, that *insects* had no hearts; whereas our microscopes do now discover, that when *insects* have several lungs, they have also several hearts; and, in particular, it is found, that silk-worms have a continued chain of hearts, reaching from the head almost to the very extremity of the tail. See *HEARTS of insects*.

It is this number of hearts and lungs that occasions those *insects* to give signs of life long after they are divided into several parts.

Andry observes, also, that it is wrong to call *insects* imperfect animals, since they want no parts either necessary or convenient for their use, to render them complete in their kind.—There are some who affirm, that the earth-worms, and those round-tailed worms which are found in the intestines of men and horses, &c. also snails and horn-leeches, are hermaphrodites; but that such worms as become flies, and silk-worms, are not so: being of no sex, but only peculiar cases of real animals, which we see, in time, come out with wings.

The moderns have proceeded much farther in the knowledge of *insects* than the ancients, as having the advantages of the microscope, which distinguishes their minute parts, whereas they have published drawings and descriptions. Dr. Hook has published a *Micrographia* in folio; and Franz Reaumur, a physician at Florence, has published several figures with new and curious experiments of his own. Sig. Malpighi, Bathonian, and the Philosophical Transactions of London, Paris, and Leipzig, have a great number of fine observations and experiments on *insects*.—Swammerdam has written a general history of *insects* in Dutch, and allures us, there were, before that, above 400 writers on this subject; among others, he speaks well of Wotton, Gesner, Aldrovandus, Moullet, Harvey, Fabricius ab Aquapendente, Geodart, &c. Hoeftnagel, painter to the emperor Rodolphus, has given very good designs of above 300 species; Geodart has described above 400, and Mr. Albin has given us a new history of the English *insects*, with beautiful figures; and since that the late Mr. Walks, and many others, have given histories and figures of many kinds.

The principal authors who have written on *insects*, or *entomologia*, besides those already mentioned, are Lister, Lady Merian, who sailed from Holland to Jamaica, in pursuit of the study of *insects*; Leewenhoeck, Penyer, Ray, Frisch, Reaumur, Linnaeus, who first undertook to determine the genera of *insects*, and assign them their proper characters, in the *Sylva Systema Naturæ*, and has reduced this science to a systematic form, Koeber, D. Geer, Adriaan Clark, Erer, Poels, Scopoli, Sulzer, Brønhius, Schob, Geoffroy, Schaffer, Harris, Brunnich, Lecker, Dier, Sep, and Pouter.

INSECTS, transformation of. It is well known that flies are not produced in that form, from the eggs of their parents, but undergo a change like that of the butterfly, and the like winged insects: the egg hatching into a worm; a case of *CATERILLAR*, called by Linnaeus *larva*, the insect being in this state masked, or having its true appearance concealed; and this, after performing all the operations of animal life for a certain time, enters into a state of rest, distinguished by the name of *chrysalis*, or *AURELIA*, and

more lately by that of *pupa*: and thence is changed into a fly, or the *imago*, as it is called by Linnaeus.

Swammerdam, to whom the world is indebted for the first true insight into the wonders of the insect-world, has evidently proved, that what had before been called by the pompous and mysterious names of changes and transformations of one animal into another, as of a worm into a fly, and the like, is, in reality, no more than a gradual and natural growth and evolution of the parts, not any metamorphosis of them; and this growth resembles very well, when judiciously considered, not only the increase of other animals, but also the natural building and increase of plants.

The progress of these changes, as they are called, in insects, is expressed by two different terms in their two most remarkable states; the words are the *symphæ* and the *chrysalis*. See *AURELIA* and *NYMPH*.

Swammerdam refers the general changes, as they are called, of the insect-tribe, into four classes, one or other of which occurs in that of every known insect, a very few excepted, whose progressions have not yet been sufficiently inquired into, to ascertain their nature. The four general classes, or ranks of changes, are distinguished by four different ways of production, change, and growth.

The first rank, which he expresses by the name of nymph-animal, hath a little animal fully formed in the egg, which, after the evaporation of the superfluous moults, comes forth perfect, and so grows up. Such is the locust, and the like.

The second class is distinguished by the name of *nympho-vermiculus*. These have the parts of the future insect imperfectly shaped in the egg, and, after hatching, leave the creature to acquire its perfection slowly by outward food. Of this kind are the grasshopper, the locust, the cricket, and many other the like creatures.

The third class he distinguishes by the name of the *nympho-chrysalis*, or *nympho-aurelia*. These, after hatching, obtain their perfection darkly, and not till after the casting off the last skin: such are the butterflies and the like. The second and third class agree in this, that not a perfect animal, but a worm, is produced from the egg; and precedes the growing of the perfect parts; yet with this difference, that in the second the little creature grows up manifestly and obviously to the eye; but in the third all in darkness and obscurity under the skin, and, as it were, within the body of the creature.

The fourth class is distinguished by the phrase *nympho-vermiformis*; and the creatures of this class remain always shut up in the case of the worm or maggot, without any possibility of discerning the parts, till casting both skins at once, it becomes a perfect and free animal, capable of propagating its species.

These insects which come forth perfect, and in their own proper form, out of the egg, suffer no future changes, but only the casting off their skins; but those which come from under the envelopment of a vermiform coat, do, besides casting their skins, after a proper time of eating and crawling about in that state, become nymphæ: and all insects, as well those which come out of the egg in the worm state, as those which come forth in their own form, are originally, in the egg, all in the nymph-form; and those which come out of the egg perfect animals, have no other difference in the manner of their productions from the others, but that they have suffered in the egg, and out of the way of our inspection, all those changes which the others do undergo in the chrysalis or nymph-state, in our sight. The parts of the nymphæ of these animals protuberant and expand themselves by degrees, much in the same manner that the buds of flowers of plants do; and the caterpillar is certainly the butterfly itself, only covered with a mantle which hides its several limbs from our eyes till thrown off.

Thus are the general tribes of insects regularly reduced to these four classes, in regard to the manner of their production. Those particular species which seem not reducible to these, or any other rules, or for which further observation at least is required, are the glow-worm, the scorpion, the julea, the weevil or curculio, the dung-beetle or pilularius scarabeus, the smallest water-beetle, and this scorpion. See these under their several heads. Swam. Hist. Insect.

Though the general course of nature is the same in this respect in flies and butterflies, yet the means and manner of it are different; the *NOCTURNAL* makes its way for this transformation; the fly-worms of many kinds have only a shell of their own proper skin to undergo this change in.

All the fly-worms of the first and second, and many of those of the third class, have their case thus made out of their own skin; the different species afford indeed some varieties in the manner of this, but a general idea of the

work may be had from observing the worm or maggot of the common fly-fly in its several stages.

When this creature has arrived at its full growth, it finds it not convenient any longer to remain among the food it has till then lived upon; it quits it and now goes in search of a place where it may wait for its metamorphosis. To this purpose it creeps into the earth, where it remains two or three days without any change; at the end of this time, instead of its pointed figure, its white colour, and soft fleshy substance, it acquires the figure of an egg, and becomes of a chestnut colour, or somewhat reddish, and looks opaque and crustaceous; it is in this state perfectly stiff, and destitute of motion, and the creature seems not only to have lost its form, but wholly to have lost its life also. This however is not the case, all that is done is that the creature has absolutely quitted its skin, which is now become hard and of a determinate figure, and is within it completing all its changes.

The manner in which this change of figure is given to the skin, is by the creature's drawing in its head, and the two or three first rings of its body, within the rest, and by that means making itself of this shape, there and equally thick at each end. It does this within a few hours after it creeps into the earth, and if taken out after that time is always found of this shape, and seems to be transformed, only that its skin has not yet acquired its brown colour. This however is not at all the case, for it can now walk as before, and thrusting out its head and the rings it had drawn in, can again acquire its former figure, which however it loses afterwards at once, and becomes rigid in a few minutes, and in two or three hours the skin it has quitted, and which is now a shell, becomes reddish, and after a little more time acquires its proper chestnut colour.

This coat is now no more a skin, but a shell, and fit to perform all the offices of one; it is no longer connected to the body of the animal, but is become hard, brittle, and rigid. It may, however, yet be distinguished, especially by the help of the microscope, to be made up of a great number of rings, which may be more distinctly counted than they could be in the worm.

The transformation in this shell is double before the insect becomes what it is to be finally, a fly like its parent; the first transformation is into an oblong mass of matter, void of all form, either of the worm it was, or of the fly it is to be; but from this it, by degrees assumes the figure of the nymph, in which all the lineaments of the future fly are distinguishable. This transformation (which is in these, and perhaps in all the worms that make a case of their own skin, prior to their change into the nymph state) may be called the change into the long ball or spheroid, or into the ellipsoide. This fly-worm of the blue fly is one of those, which with most difficulty shews this transformation; but on boiling it at a proper time, and afterwards carefully opening the shell, it will always be found in this state.

The time required for these several changes often differs a little, and sometimes considerably; but at a medium it stands thus: the worms which have been seen to creep into the earth on the 21st of April, have come out perfect flies on the 16th of May, and that in a cold season for the time of the year.

The changes a multitude of other fly-worms undergo, and their shells made of their proper skin, are the same in all essential points with those of the flies first mentioned. Some species have their shell more deeply annular, others almost entirely smooth; some have the two ends somewhat pointed, and others only one of them so; and in some this larger inflated end is the anterior, and in others the posterior. Reaumur's Hist. Insect. iv. p. 283, &c.

INSECT, *Antennæ* of. The insect world affords us numerous uses, and those many of them such as no one would at first thought imagine, and which no other operation or operators could so well effect. In the minutiae of anatomy, where knives cannot be introduced, the maggot or the ant may be employed with great success. Selections of insects have been prepared by burying them in an ant-hill, and that in so accurate and perfect a manner, that all who have seen them, have admired by what means they could be so nicely finished; and the secret of the great Rosch, by which he cleared away the parenchymatous substance from his vascular preparations, was of this kind. After injecting the vessels of any part with wax, all that remained to the completing these preparations, was the taking off the parenchymatous or fleshy matter from between and among them. Other zoologists of his time did this by the knife, or by maceration in water and other liquors; but it appeared a sort of magic to them, that his were always not only much sooner executed, but to a greater nicety and perfection than

than their's ever possibly could be. His method was only to put a number of the common flesh-eating maggots, to the substance; and these regularly eat away all the flesh, their heads getting into crevices which no instrument could reach, and the whole substance of the infection remained unharmed, as their soft bodies could glide between its niches parts without injuring them; and the wax being no food for them, was in no danger of being eroded, even in its softened places. The several sizes of the worms or maggots bred from the eggs of different flies were of great use in the perfecting the preparations; for while the larger first eat the more fleshy parts, where the vessels are large and but few in number, the middle-sized maggots get into the interstices of the more vascular parts, and the most minute of all, which are usually also the most numerous, kept about the surface, and eat away between and among the capillary vessels.

The maggots produced from flies are not the only animals fit for this kind of business. There are several species of beetles of the smaller kinds, whose eggs hatch into a six-legged worm, which eats as much and as nicely as the fly-maggots. All these may be employed very successfully to the preparation of the parts of animals.

These nice anatomists are not confined to animal substances: they often exert their power also on vegetables. Many of them feed on the leaves and fruits of plants; and some species of these work so nicely, that they eat away all the outer membrane and internal parenchyma substance of the leaves, so as only to leave the net-like veins of vessels standing. Yet these being unharmed, they are the true figure of the leaf, and are a sort of vegetable skeletons, but very poorly imitated by art in the common way, by long macerations in water; this method usually destroying and washing away many of the smaller vessels, which the tender mouths of these creatures spare. If they exert their skill often upon leaves in this manner, they do it also sometimes with equal if not greater success upon fruits. As in the leaves, those which have the tenderest parenchyma and the firmest rind, succeed best; so also it is in fruits. The leaves of the rufous or butcher's-bee, are often found thus beautifully anatomized; and of all fruits, none succeeds so well as that of the stramonium, or thorn apple. Wherever this plant grows in any plenty, the fruit towards autumn, while it is yet full of juice, is attacked by a small worm, which eats away all the parenchyma, and leaves every vessel standing in its place; and this not only in the outer coat of the fruit, but in the very inner cells of the seeds. These vessels remain exactly in the shape of the fruit, and growing white with the air, exhibit the most elegant and beautiful skeletons imaginable, while yet standing on the plant. The animal which effects this, is a hexapode worm produced from the egg of a small beetle; and differs very little from some of those which so elegantly eat away the fleshy parts from the injected anatomical preparations. These are gregarious animals like some species of the smaller caterpillars, and numbers of them are always at work together on the same leaf, or fruit, so that the skeleton is soon made. They begin by piercing a number of little holes into the substance of the leaf, and thence burrow under the integument till they meet one another; and this being done all over the leaf, they leave it, and go to work upon another.

INSECT, *Aleph*, a term used by some to express the capricious, or mischievous; but it is too loose a phrase for that animal, since there are other insects which smell as strongly of that perfume. There is a small kind of bee, very frequent in the pastures of Lincolnshire, and several other parts of England, in April this frequents the ranunculus and dandelion flowers, and has a very strong and fine scent of musk: there is also a hexapode worm, which feeds on the *gallium ulinum*, or yellow ladies bed-stew, which has the same perfumed scent in a less degree. Both these insects, and even the capricious beetle, lose their perfume when they have been some time dead. Phil. Trans. N^o 76.

INSERTED cilium. See CILIUM.

INSERTION, a term frequently used, in *Anatomy*, to signify the implication of one part within another. Thus we say, the *insertion* of a muscle.

The *insertion* of the bones, muscles, and nerves in the members of an animal, is exceeding artificial; the veins have no *insertion* in the right ventricle of the heart.

INSERTION is also used, in *Agriculture*, for the inclosing a graft within the cleft of a tree. See ENGRAFTING.

INSESSUS, or INSESSIO, in *Medicine*, a kind of half bath, or REMICUTATIO, usually prepared with a decoction of febrile herbs proper for the lower parts, wherein the patient lies down to the navel.

It has several uses: as the easing of pain, softening the parts, dissolving a stasent matter, and frequently promoting the menses.

INSIDIAN *disguis*, a term used by some authors, to express such diseases as shew no evident symptom, but remain latent a long time in the body, and are ready to break forth in an unexpected manner, and as it were by surprise.

INSINUATION denotes a cunning, and covert way of creeping into any person's favour.

INSINUATION of a *wind*, among *Circians*, is the first production of it, or the leaving it with the regiller, in order to its probate. See WIND.

INSIPID, *insipidus*, that which has nothing in it pungent enough to affect the palate, tongue, &c. and to occasion that sensation we call *tasting*.

INSITION, INSITIO, in *Botany*, denotes the same with ENGRAFTING; viz. the act of inserting and uniting a cyon, bud, or the like, in the substance of the stock.

INSOLATION, in *Pharmacy*, a method of preparing certain fruits, drugs, &c. by exposing them to the heat of the sun's rays; either to dry, to mature, or to sharpen them; as is done in vinegar, figs, &c.

The word comes from the Latin verb *insolare*, which is used by Pliny and Columella; and signifies *to expose to the sun*.

INSOLVENT, a term applied to such persons as have not wherewithal to pay their just debts.

A person dying, and not leaving estate sufficient to discharge these, is said to die *insolvent*.

INSPECTOR, a person to whom the care and conduct of any work is committed.

INSPECTORS, in the *Roman law*, were such persons as examined the quality and value of lands and effects, in order to the adjusting or proportioning taxes and impositions to every man's estate.

The Jews also have an officer, in their synagogues, whom they call *inspector*, *חזן*, *blazan*. His business consists principally in *inspecting*, or overlooking the prayers and lessons, in preparing and shewing them to the reader, and in standing by him to see he reads right; and, if he makes mistakes, he is to correct him.

INSPICIENDO vestes. See VESTES.

INSPIRATION, among *Divines*, &c. implies the conveying of certain extraordinary and supernatural notices, or motions, into the soul: or, it denotes any supernatural influence of God upon the mind of a rational creature, whereby he is formed to any degree of intellectual improvements, to which he could not, or would not in fact have attained in his present circumstances in a natural way.

Thus the prophets are said to have spoken by divine *inspiration*.

Some authors reduce the *inspiration* of the sacred writers to a particular care of Providence, which prevented any thing they had said from failing, or coming to naught; maintaining that they never were really inspired, either with knowledge or expression.

According to M. Simon, *inspiration* is no more than a direction of the Holy Spirit, which never permitted the sacred writers to be mistaken.

It is a common opinion, that the *inspiration* of the Holy Spirit regards only the matter, not the style, or words; and this seems to fall in with M. Simon's doctrine of dictation.

Theological writers have enumerated several kinds of *inspiration*: such as the *inspiration* of superintendency, in which God does to influence and direct the mind of any person, as to keep him more secure from error in some various and complex discourse, than he would have been merely by the use of his natural faculties; plenary superintendent *inspiration*, which excludes any mixture of error at all from the performance to superintended; *inspiration* of elevation, where the faculties act in a regular, and, as it seems, in a common manner, yet are raised to an extraordinary degree, so that the composition itself, upon the whole, have more of the true sublime, or pathetic, than natural genius could have given; and *inspiration* of suggestion, when the use of the faculties is superseded, and God does, as it were, speak directly to the mind, making such discoveries to it as it could not otherwise have obtained, and directing the very words in which such discoveries are to be communicated, if they are designed as a message to others.

It is generally allowed that the New Testament was written by a superintendent *inspiration*; for without this the discourses and doctrines of Christ could not have been faithfully recorded by the evangelists and apostles; nor could they have assumed the authority of speaking the words of Christ, and evinced this authority by the actual exercise of miraculous powers; and besides, the sacred writings bear many obvious internal marks of their divine original, in the excellence of their doctrines, the spirituality and elevation of their design, the majesty and simplicity of their style, the agreement of their various parts, and their efficacy on mankind; to which may be added, that there has been in the Christian church, from its ear-

left ages, a constant tradition, that the sacred books were written by the extraordinary assistance of the spirit, which must at least amount to superintendent inspiration. But it has been controverted whether this inspiration extended to every minute circumstance in their writings, so as to be in the most absolute sense plenary. Jerom, Grotius, Erasmus, Episcopius, and many others, maintain that it was not; whilst others contend, that the emphatical manner in which our Lord speaks of the agency of the spirit upon them, and in which they themselves speak of their own writings, will justify our believing that their inspiration was plenary, unless there be very convincing evidence brought on the other side to prove that it was not; and if we allow, it is said, that there were some errors in the New Testament, as it came from the hands of the apostles, there may be great danger of subverting the main purpose and design of it; since there will be endless room to debate the importance both of facts and doctrines.

Among the Heathens, the priests and priestesses were said to be divinely inspired, when they gave oracles. The poets, also, laid claim to it; and, to this end, they always invoked Apollo and the Muses, at the beginning of any great work.

INSPIRATION, in *Physic*, is understood of that action of the breath, by which the air is admitted into the lungs. In which sense, *inspiration* is a branch of respiration; and stands opposed to *expiration*.

This admission of the air depends immediately on its spring, or elasticity, at the time when the cavity of the breast is enlarged by the elevation of the thorax and abdomen, and particularly by the motion of the diaphragm downwards: so that the air does not enter the lungs, because they are dilated; but those dilate, because the air enters within them. Nor is it the dilatation of the breast, which draws in the air, as is commonly thought; though this is a condition absolutely necessary to *inspiration*; but there is an actual intrusion of the air into the lungs.

INSPISSATING, in *Pharmacy*, an operation whereby a liquor is brought to a thicker consistence, by evaporating the thinner parts.

Thus, juices, as that of liquorice, are *inspissated*.

INSTALLMENT, a settling or inhaling, a person in a dignity.

The word is derived from the Latin *in*, and *stallum*, a term used for a seat in church, in the choir, or a seat or bench in a court of justice, &c. though *Votius* is of opinion, the word is of German origin.

Installation is chiefly used for the induction of a dean, prebendary, or other ecclesiastical dignitary, into the possession of his stall, or proper seat, in the cathedral church to which he belongs.

This is sometimes also called *installation*.

Installation is likewise used for the ceremony, whereby the knights of the *GARTER* are placed in their rank, in the chapel of St. George, at Windsor; and on many other like occasions.

INSTANT, such a part of duration, wherein we perceive no succession; or it is that which takes up the time of only one idea in our minds.

It is a maxim, in *Mechanics*, that no natural effect can be produced in an *instant*.—Hence may appear the reason, why a burthen seems lighter to a person, the faster he carries it; and why, the faster a person slides, or skates, on the ice, the less liable is the ice to break.

The schoolmen distinguish three kinds of *instants*; a temporary, a natural, and a rational *instant*.

INSTANT, temporary, is a part of time immediately preceding another: thus the last *instant* of a day, precedes immediately and really the first *instant* of the following day.

INSTANT, natural, is what we otherwise call a *priority of nature*, which obtains in things that are subordinated in acting: as, first and second causes; or causes and their effects: for the nature of things requires, that if there be a second cause, there must be a first; and that there must be a cause, if there be an effect.

INSTANT, rational, is not any real *instant*, but a point which the understanding conceives to have been before some other *instant*, founded on the nature of the things which occasions it to be conceived. For instance; as God has made several things voluntarily, which he could otherwise have let alone; there is a reasonable foundation to conceive God, such as he is in himself, before he had made any of those voluntary determinations; but as there was no real *instant* when God had not so formed any determination, this *instant* is called a *rational instant*, by way of opposition to an *instant* of time.

INSTANTANEOUS action. See *ACTION*.

INSTAURATION, the re-establishment, or reformation, of a religion, a church, or the like, to its former state.

The word is by some derived from the old Latin, *inflatus*. Vol. II. N° 187.

rum, which signified the stock of things necessary for the tilling and managing of grounds; as cattle, tools, harness, &c. The word *instaurum* is only of the middle age; but *instauratio* is of much greater antiquity, and by some is derived from *instare*, *lat.*; as importing a thing's being brought to its former likeness, or appearance.

INSTEEL, in the *Almagest*, is that part of the hinder leg of a horse, that corresponds to the flank in the fore-leg, extending from the hump to the pastern joint.

INSTINCT, a natural disposition, or sagacity wherewith animals are endued; and by virtue whereof they are enabled to provide for themselves, and know what is good for them, and are determined to preserve and propagate their species.

Instinct in brutes, bears some analogy to reason in men.

There have been many systems adopted to explain the principles which produce and direct the spontaneous actions of brute animals.

Many of the ancient philosophers ascribed to brutes an understanding, differing only in degree from that of man, and attributed their inferiority to the want of proper and sufficient bodily organs. This system has been lately very strenuously supported by M. Helvetius, de l'Esprit, tom. i. p. 2. &c. Among the moderns, the learned Cudworth endeavoured to explain the *instinct* of animals, by means of a certain *plastic nature*. Des Cartes thought that all the actions of brute animals might be explained by the simple laws of mechanism, and considers them as machines totally devoid of life and sentiment, but so curiously constructed by the Creator, that the mere impressions of light, sound, and other external agents, on their organs, produced a series of motions in them, and caused them to execute those various operations, which had before been ascribed to an internal principle of life and spontaneity. But the actions and manners of animals, which are totally incompatible with the mere principles and laws of mechanism, evince the absurdity of this opinion. M. Buffon adopts the opinion of Des Cartes in part, but grants them life, and the faculty of distinguishing between pleasure and pain, together with a strong inclination to the former, and aversion from the latter. By these inclinations and aversions he undertakes to account for all, even the most striking operations of animals; affirming, that in consequence of impressions made on the brain, by means of the sensitive organs, and by the reaction of the brain and nerves on the muscles, these machines acquire a motion conformable to the nature of the animal, and of the impressions of the different objects which act upon their organs, and excite desire or aversion. See *BEHAVIOUR*.

The pre-established HARMONY of Leibnitz has also been applied to explain the actions of brute animals. Others have considered the actions of animals as produced by the constant and immediate influence of the divine energy, directing all their inclinations and motions: such appears to have been the opinion, however unphilosophical it must appear, of Mr. Addison, in the second volume of the *Spectator*. The late ingenious Hermann Samuel Reimar, professor of philosophy at Hamburg, has enumerated and exposed these and other opinions, with regard to the *instinct* of animals, in his *Observations Physiques*, &c. published in two vols. 12mo. at Amsterdam and Paris, 1770: and, defining *instinct*, in the most comprehensive sense of the word, to be every natural inclination, accompanied with a power, in animals, to perform certain actions, divides *instincts* into three heads. The first, which he calls *mechanical instincts*, belong to the body, considered as an organized substance, and are exercised blindly and independently of the will of the animal. Such are those which produce the motion of the heart and lungs, the contraction and dilatation of the pupil, digestion, &c. This class of *instincts* is possessed in common both by men and brutes, and in some measure even by vegetables. The second class comprehends those which he terms *representative instincts*, which consist partly in the power of perceiving external objects by their present impression on the senses, and partly in the faculty of rendering the ideas of these objects present to the mind by the powers of imagination, or of memory, in a lax sense of the word. These are common to men and other animals, excepting that brutes possess only the faculty of imagination in common with us, and not that of memory, in the strict and proper sense of the word. Indeed this author endeavours to prove, that the knowledge of brutes does not merely differ in degree from that of man, but that it is of a kind entirely different from it; and that they are incapable both of memory and reasoning: the faculty of imagination serving to give them a confused idea of events that are past, by the view, or other impressions of objects that are present. The third and principal class of *instincts* is that which comprehends all those which M. Reimar calls *spontaneous*. This

species of *instinct* is not attended with any power of reflection, determining the animal to decide freely between two different modes of action present to his imagination; nor is it merely corporeal or mechanical. It is set into action by the natural and primitive principle of self-love, implanted in all animated beings; or by a love of pleasure and aversion to pain, producing a voluntary inclination to perform certain actions which tend to their well being and preservation. To the performance of these actions they are particularly prompted by their present sensations, by imagination supplying the place of memory, and by other causes. The wonderful effects produced by these instinctive appetites, are farther to be attributed to the exquisite mechanism in their bodily conformation, particularly in the structure of the various organs with which they execute their operations, and to the superior perfection and acuteness of their external senses, by which they are quickly and distinctly informed of those qualities of objects which most materially concern them. In order to account for the more curious and surprising operations of brute animals, M. Reimar adds two other principles, viz. 1st. an internal distinct perception of the precise power and proper use of their various bodily organs, together with an innate knowledge of the qualities of those objects around them in which they are interested; and, 2dly, certain innate and determinate powers and inclinations, impressed by the Author of Nature, *a priori*, on the soul itself; by which they are arbitrarily, and without their own knowledge, or consciousness, directed and irresistibly impelled to the performance of these various operations which they execute with such unerring industry and art. These determinate forces, which constitute the principal part of M. Reimar's system, are not where so visible and distinguishable as in that numerous set of *instincts* which he classes under the title of the *instinctive* of brute animals. For a farther account of this system we must refer to the work itself, or to an abstract of it, with several of the author's illustrations, in the Monthly Review, vol. xlv. p. 533, &c.

INSTITA, a word used by the chirographical writers, for a fillet or other badge of that kind; and by medical writers, for that sort of flat worms bred in the intestines, called by many the tape-worm, or flat worm.

INSTITUTES, **INSTITUTA**, in the *Civil Law*, a book, containing the elements, or principles of the Roman law; and which constitutes the last part of the *corpus juris civilis*.

The *Institutes* are a compendium, or summary of the whole body of civil law, in four books, composed by Trebatianus, Theophilus, and Dorotheus, by order of the emperor Justinian, for the use of young students; who, having the first elements of the whole profession in this little treatise, might the sooner gain a competent knowledge of it, without being discouraged by the bulk of the other books. See *CIVIL LAW*.

INSTITUTE likewise denote a system of laws or rules, in any science.

INSTITUTION, in a general sense, the act of ordaining, founding, or establishing, any thing.

Thus we say *Moses instituted* the ceremonies of the old law; *Jesus Christ instituted* the sacraments of the new.

INSTITUTION, in the *Canon and Common Law*, is the act of the bishop, or of one commissioned by him, whereby a clerk is invested with the spiritualities of a rectory, or vicarage. See **PRESENTATION**.

The clerk kneels down before the bishop, whilst he pronounces these words of *institution* (*Instituo te rectorem ecclesie de A. B. cum cura animarum, & accipe curam tuam & meum*); and the clerk holds the written instrument, with the episcopal seal annexed, in his hand, during the ceremony.

Before the clerk is instituted, he must subscribe the thirteenth articles of religion, in the presence of the ordinary, or his substitute; and this subscription must be without reserve, exception, or qualification; else his *institution* is, *in jure*, void and null, and the church still vacant. 13 Eliz. c. 12.—At the same time the ordinary requires the clerk to subscribe the other two articles mentioned in the 35th canon about the king's supremacy, and the lawfulness and use of the liturgy: the clerk must also, before *institution*, subscribe to that part of the declaration enjoined by the act of uniformity, 14 Car. II. c. 24. viz. *I will conform to the Liturgy of England, as by law established*.—Before *institution*, he must also take the oath mentioned in the first statute of William and Mary, c. 8. instead of the former oaths of allegiance and supremacy, required by stat. 1 Eliz. and then he must take the oath against simony, enjoined by the 40th canon, and the oath of canonical obedience; and if it is a vicarage, the oath of personal residence; and he is to have certificates given him of his subscribing the declaration contained in

the act of uniformity, in English, in a distinct instrument, under the hand and seal of the bishop; and of his other subscriptions and oaths, in Latin.

The clerk ought by all means to have witnesses of his *institution*, his taking the oaths, making subscriptions, &c. and therefore he should desire some person to write their names on the back of his instruments, and make memorandums who they are, and where they live.

The church, by *institution*, is full again! all persons but the king; and the clerk by it may enter into the glebe, and take the tithes; but he cannot let or grant them, nor sue for them, if they be refused to be paid, till he be inducted.

After *institution*, the clerk is to receive a written mandate from the ordinary to the archdeacon, or other proper person, in order to his induction; without which he has not a full right to his temporalities, unless the benefice be a donative. See **INDUCTION**.

INSTITUTIONS, in *Literary Matters*, denote a system of the elements, or rules, of any art or science. Such are *institutions* of medicine, *institutions* of rhetoric, &c.

INSTITUTOIRES, in *Beaury*, that set of authors in this science who have laid down certain settled rules, axioms, and institutions in it.

INSTRUCTIVE column. See **COLUMN**.

INSTRUMENT denotes a thing which is subservient to a cause for producing its effect.

A common case of mathematical instruments contains several compasses, a sector, scale, drawing pen, and protractor. A case of surgeon's instruments for the pocket contains different sized lancets, scissars of several kinds, plain and toothed forceps, straight and crooked section-knives, a spatula, probe, needles, &c. Astronomical instruments, as the Telescope, Quadrant, &c. Chemical instruments, see **LABORATORY**.

INSTRUMENTS of Justice, in the *Antient Architecture*, are ornaments, as vases, paterae, candlesticks, knives, &c. wherewith the victims were killed, &c. instances of which we see in a Corinthian frieze in the remains of a temple behind the Capitol at Rome, &c.

INSTRUMENT is also used, in *Law*, to signify some public act, or authentic deed, by means wherof any truth is made apparent, or any right or title established, in a court of justice.

INSTRUMENT, *wind*. See **WIND**.

INSTRUMENTAL arithmetic. See **ARITHMETIC**.

INSTRUMENTAL cause. See **CAUSE**.

INSTRUMENTUM simulacri. See **SYNOCHALE**.

INSUFFLATIO, a term used by some writers in medicine, to express the blowing into any part, in order to convey the fumes of medicines into it.

INSULATE, or **INSULATED**, a term applied to a column, or other edifice, which stands alone, or free and detached from any contiguous wall, &c. like an island in the sea; whence the denomination is apparently derived.

INSULATED, in *Electricity*, is a term applied to bodies that are supported by **ELECTRICE** or **NON-CONDUCTORS**; so that their communication with the earth, by conducting substances, is interrupted.

INSULT, in *Law*. See **ASSAULT**.

INSULT, a military term used for the attack of any post with open force; without the apparatus of trenches, saps, or any regular approaches. See **ASSAULT**.

INSULTUS, a word used by the writers in medicine, to signify the access of the paroxysm in intermittent diseases; or, sometimes the first invasion of a disease.

INSUPER, a word used by the auditors of the Exchequer. In their accounts they say, so much remains *insuper* to such an accountant; that is, so much remains due on his account.

INSURANCE, or **ASSURANCE**, in *Law*, and *Commerce*, a contract, or agreement whereby one or more persons, called *insurers*, &c. oblige themselves to answer for the loss of a ship, house, goods, &c. specified in the policy of *assurance* subscribed by them, in consideration of a premium, of a stipulated sum per cent. paid by the proprietors of the things insured.

Sistorius conjectures, that the emperor Claudius was the first contriver of *insurance* on ships and goods. The first instance recorded in most modern history of this practice, is in the year 1565, on occasion of the vast woollen commerce between England and the Netherlands, though it was probably in use before this time, and is said to have been introduced by the Jews in 1182; and it is treated of in the Sea-laws of Oléron, as early as the year 1194. The first English statute relating to it is the 43 Eliz. c. 12. It is supposed to have been introduced into England, and soon after into Antwerp, by some Italian settlers from Lombardy. The merchants at this time met in a place, where Lombard-street now is, called the Paven-house, or Lombard, where they issued policies of *insurance*; to which the subsequent practice referred.

Insurances are of various kinds, as on ships or parts of ships, on merchandize singly, and on ships and goods jointly: and these are again branched out to run either for a time stipulated, or to one single port, or out and home, with liberty to touch at the different places mentioned in the policy. *Insurances* may likewise be made on goods sent by land, or by boys, &c. on rivers; and this is frequently done, more especially on jewels, and other things of great value. They may likewise be made on ships and goods, lost or not lost, which is commonly done when a ship has been long missing; and those words being inserted in the policy, oblige the under-writers to pay, though the ship was lost at the time of making such *insurance*, except the assured had then certain knowledge of the ship's being wrecked; in which case the subscription shall not oblige, as this is accounted a mere fraud. So likewise if a person get more insured than the ship is worth, with a villainous design to destroy her, this fraudulent act will not oblige the insurers, but expose the proprietors to suffer death for their knavery. If a ship is insured from the port of London to any foreign port, and before the breakers ground is burnt, the insurers are not liable; unless the words of the *insurance* are, as from the port of London; but if the ship once broke ground, and after being driven back, takes fire, the insurers are answerable. An *insurance* made on prohibited goods is not binding, unless they were not prohibited till after the *insurance* was made. Where the policy expressly mentions that the ship is to depart with convoy, it is intended that the ship, if possible, keep with the convoy during the voyage, and if she depart willfully from the convoy, it is a fraud; but if having departed with convoy, she is struck by weather loses the convoy, and is taken, the insurers are liable. If there be thieves on board among themselves, the master of the ship is to answer for that, and not the insurers; for though the words of the policy insure against losses by thieves, yet assailing thieves are only here intended. An *insurance* made in a foreign country, may be sued in England by the common law, if the insurers come here. Where the policy is against restraint of princes, that does not extend to a navigation carried on against the law of nations, or where there shall be a seizure for not paying of customs, or the like. If goods be insured as the goods of an ally, when they are the goods of an enemy, it is a fraud, and the *insurance* not good. If a man pays money on a policy of *insurance*, supposing a loss where there was none, this shall be money received for the use of the insurer, for which he may maintain an action. Damages happening to goods in their own nature perishable, are not to be borne by the insurers. A suppression of the truth, or a false allegation, is sufficient to discharge the policy; for it is a general rule, that the insured ought to inform the insurer of all material circumstances that were come to his knowledge at the time of making the policy, in order that the contract may be fairly adjusted; which being a contract upon chance, cannot be done, if one party knows more than the other; for equality in contracts, by the law-merchant, is essential; but a proof of an intention to make a deviation, will not avoid the policy before the deviation is actually made. By an act made in 19 Geo. II. c. 37, it is determined, that after the first day of August, 1746, no *insurance* shall be made on ships or lading by way of gaming or wagering, or without benefit of salvage to the insurer: that it shall not be lawful to make re-*insurance*, unless the insurer shall become insolvent, become a bankrupt, or die; in which cases such insurer, or his executors, &c. may make re-*insurance* to the amount of the sum before af-

fured, provided it be expressed in the policy to be a re-*insurance*. That all sums of money lent on bottomry or at respondentia, upon any ships belonging to his majesty's subjects, bound to and from the East Indies, shall be lent only on the ship or merchandize, laden, or to be laden, on board such ship, and shall be so expressed in the condition of the bond; and the benefit of salvage shall be allowed to the lender, his agent or assigns, who alone shall have a right to make *insurance* on the money so lent; and no borrower of money on bottomry, &c. shall recover more on any *insurance* than the value of his interest in the ship or merchandize, exclusively of the money so borrowed; and in case it shall appear, that the value of his share in the ship and merchandize does not amount to the full sum borrowed, such borrower shall be responsible to the lender for so much of the money borrowed, as he hath not laid out on the ship or merchandize, with lawful interest for the same, together with the *insurance* and all other charges, to the proportion which the money not laid out shall bear to the whole money lent, notwithstanding the ship and merchandize be totally lost.

Whenever advice is received of the loss of a ship or goods insured, application is to be made to the insurers, and the vouchers produced; and if they are satisfied they will pay the money; but if they have cause to scruple the doing it, the insured must stay till the insurers can obtain a more satisfactory account; but if nothing be heard of the ship in any reasonable time, the insurers will be obliged to pay the money agreed upon.

The policies made of *insurances* are to be stamped within three days after the ship is insured, on the penalty of paying 100l. The principal offices for the *insurance* of ships and merchandize in London, are the Royal-exchange *Assurance*, and the London *Assurance*, both of which are established by act of parliament, 6 Geo. I. c. 18. anno 1720. These offices also insure houses and other buildings, goods, wares, and merchandize, from loss or damage by fire; and they also insure lives.

The Royal-exchange *Assurance*, on a brick or stone building, insures any sum not exceeding 300l. at 5s. per ann. and any larger sum not exceeding 1000l. after the rate of 2s. 6d. per cent. per ann. Above 1000l. and not exceeding 2000l. at 3s. per cent. Above 2000l. and not exceeding 3000l. at 4s. per cent. On goods and merchandize, the property of the assured, within any brick or stone building, or on the goods and building together, this office insures any sum not exceeding 300l. for 7s. 6d. per ann. and larger sums after the rates above mentioned: but timber or plaster-buildings, or goods or merchandize therein pay 8s. per ann. for 200l. and after the rate of 4s. per cent. for any greater sum not exceeding 1000l. and 5s. per cent. for all *insurances* above 1000l. and not exceeding 2000l. On a timber or plaster building with goods and merchandize together, any sum not exceeding 300l. may be insured for 12s. per ann. and larger sums at the above rates. The goods belonging to hazardous trades, as distillers, chemists, apothecaries, colour-men, tallow-chandlers, oil-men, innholders, &c. deposited in brick houses, pay 8s. per ann. for insuring 200l. and after the rate of 4s. per cent. for any greater sum not exceeding 1000l. and above 1000l. and not exceeding 2000l. 5s. per cent. but when the houses and goods are put together, the price of *insurance* is 4s. per cent. per ann. without any other charge except the policies.

The London *Insurance* has the following annual premiums:

Sums assured.	Common insurances.	Hazardous insurances.	Double hazardous insurances.
Any sum.			
Not exceeding 200l.	4s. per annum.	6s. per annum.	10s. per annum.
From 200l. to 1000l.	3s. per cent.	3s. per cent.	5s. per cent.
From 1000l. to 2000l.	2s. 6d. per cent.	4s. per cent.	7s. 6d. per cent.
From 2000l. to 3000l.	4s. per cent.	6s. per cent.	7s. 6d. per cent.

The Hand-in-hand office, erected in 1696, and entailed in decerny in 1698, insures for seven years at 10s. deposit, and 2s. premium per cent. on brick and stone, and double that sum for timber-houses, the sum not exceeding 1200l. And for any sum from 1200l. to 2000l. 4s. per cent. on brick or stone, and double on timber houses, for any term of years not exceeding seven. But a sum exceed-

ing 2000l. is not to be insured on any building, without the approbation of a general court; and the office insures only three fourths of the value of each house. To this office belong thirty firemen.

The Sun-fire-office, established in 1710, besides 7s. 6d. for the policy and mark, has the following annual premiums:

Sums insured.	Common insurances.	Hazardous insurances.	Double hazardous insurances.
Any sum.			
Not exceeding 200l.	4s. per annum.	6s. per annum.	10s. per annum.
From 200l. to 1000l.	2s. per cent.	3s. per cent.	5s. per cent.
From 1000l. to 2000l.	2s. 6d. per cent.	4s. per cent.	7s. 6d. per cent.
From 2000l. to 3000l.	4s. 6d. per cent.	5s. per cent.	7s. 6d. per cent.

The common *insurances* comprehend all brick or stone buildings not occupied by hazardous trades or goods. The hazardous *insurances* are on timber-buildings, and goods and merchandises in them called hazardous. The double hazardous are thatched timber or plaster buildings, wherein hazardous good or trades are kept or carried on. The hazardous trades and goods are apothecaries, chemists, bakers, ship and tallow-chandlers, stable-keepers, inn-holders, and malt-houses; hemp, flax, tallow, pitch, tar, turpentine, hay, straw, fiddels of all sorts, and corn unthrashed. To this office belong thirty fire-men, and twenty porters.

The Friendly Society *Insurance*, or Union fire-office, erected in 1714, and enrolled in chancery in 1715, is formed on the same model as that of the Hand-in-hand fire-office, excepting that instead of houses this office only insures goods and merchandises at the following rates:

Besides the parliamentary stamp-duties, and the charge of policy and mark, which is 9s. 6d. for every 100 l. insured on goods inclosed in brick or stone, 10s. deposit, and 2s. premium; if half hazardous, 2s. to situation and kind of goods, 15s. deposit, and 3s. premium; if hazardous, 20s. deposit, and 4s. premium; if hazardous and half hazardous, 25s. deposit, and 5s. premium; if hazardous and hazardous, 30s. deposit, and 6s. premium. For every 100 l. insured on goods inclosed in part brick and part timber, 12s. 6d. deposit, and 2s. 6d. premium; if half hazardous, 18s. 9d. deposit, and 3s. 9d. premium; if hazardous, 25s. deposit, and 5s. premium; if hazardous and half hazardous, 11. 11s. 3d. deposit, and 6s. 3d. premium; if hazardous and hazardous, 11. 17s. 6d. deposit, and 7s. 6d. premium. For every 100 l. insured on goods inclosed in timber, 15s. deposit, and 3s. premium; if half hazardous, 11. 2s. 6d. deposit, and 4s. 6d. premium; if hazardous 30s. deposit, and 6s. premium; if hazardous and half hazardous, 11. 17s. 6d. deposit, and 7s. 6d. premium; if hazardous and hazardous, 21. 5s. deposit, and 9s. premium. For every sum from 1000 l. to 2000 l. the society requires a double premium; and from 2000 l. to 3000 l. a treble premium, to be computed according to the above rates. In this society every one of the assured is admitted to an equal share of the profit or loss in proportion to his *insurance*. The society has a demand on every member of 10s. per cent. and no more, in case of extraordinary losses and charges. The twenty-four directors employ as many porters as they think fit: their number is usually twenty-four.

We have also *insurances* for lives, in virtue of which, when the person insured dies, a sum of money becomes payable to the person on whose behalf the policy of *insurance* was granted. The principal *insurance* offices of this kind, are those of the Amicable Society for a Perpetual Assurance, kept in Serjeant's Inn, Fleet-street, London; and the Equitable Assurance-office, near Black-fruits bridge. See ASSURANCE.

INACTIA, right lines to which curves do continually approach, and yet can never meet with them; more usually called ASYMPTOTES.

INTAGLIOS, precious stones, having the heads of great men, inscriptions, and the like, engraven on them; such as we frequently see set in rings, seals, &c.

INTAKER, a name anciently given to certain banditti, or free-booters, who inhabited part of the North of England, and made frequent incursions into the very middle of Scotland; plundering the inhabitants wherever they came.

Those who made the expeditions, were called *out-porters*; and those who were left behind to receive the booty, *intakers*. q. Hen. V. c. 7.

INTEGERS, in Arithmetic, denote whole numbers; in contradistinction to fractions.

Integers may be defined to be, numbers which refer to unity, as a whole to a part.

INTEGRAL, or INTEGRANT, is applied by the schoolmen to those parts which are necessary to the integrity of a whole. In which sense they stand contradistinguished from *elemental* parts.

Thus the arms, legs, &c. are *integral* parts; body and soul, essential parts of a man.

INTEGRAL calculus, in the *New Analysis*, is the counter part to the differential calculus.

This last has been completely explained by the marquis de l'Hospital; but the other still remains imperfect, having been yet but little cultivated.

The *integral calculus* of Leibnitz, and other foreigners, answers to what the English call *inverse method of fluxions*. See FLUXIONS, and CALCULUS.

INTEGRANT parts, in Philosophy, the similar parts of a body, or parts of the same nature with the whole: as filings of iron are *integrant* parts of iron, and have the same nature and properties with the bar they were filed off from. The chemists distinguish, in their resolutions

of bodies, between the dividing and resolving them into *integrant* parts like these, and what they call constituent parts; that is, dissimilar parts, or the principles of the bodies they work upon. Thus when crude mercury is dissolved in aqua fortis, though held imperceptibly in the menstruum, yet when that menstruum is diluted with water, and a copper plate is suspended in it, the menstruum leaves the mercury, to work upon the copper, and the mercury sublimed unaltered and in its own natural form: the mercury therefore, in this operation, was only divided into its *integrant* parts, or small parcels of the same nature and properties of the whole; but when artificial cinnabar is resolved or divided into crude mercury and sulphur, neither of these are of the same nature and properties with the cinnabar, and are not its *integrant* but its constituent parts. This therefore is the dividing a body into its constituent parts or principles.

INTEGRITY of the skin. See ACTION.

INTEGNUM *filum*, among Botanists. See LEAF.

INTEGNUM, in zoology. See ANATOMY.

INTEGUMENTS, formed of *in*, and *tegumentum*, of *tepe*, to cover, in Anatomy, denote the common coverings which invest the body; as the cuticula, cutis, and even the panniculus carnosus, and tunica reticularis, if there be really any such part.

INTEGUMENT is also extended to the particular membranes which invest certain parts of the body; as the coats or tunics of the eye.

INTELLECT, a term used among philosophers, to signify that faculty of the soul usually called the UNDERSTANDING.

The Peripatetics make two kinds of *intellect*; *active*, and *passive*. See IDEA.

INTELLECTUAL thinking. See THINKING.

INTELLIGIBLE, any thing capable of being understood, or conceived, by the mind.

Philosophers have invented certain beings which are purely *intelligible* and only subsist in the understanding; such are the *entia rationis*, universal ideas, and other chimeras.

The *intelligible*, or intellectual world, is the idea of the world in the divine mind, frequently spoken of by Malebranche.

INTENDANT, one who has the conduct, inspection, and management, of any thing.

This is a title frequent among the French; they have *intendants of the marine*, who are officers in the sea-ports, whose business it is to take care that the ordinances and regulations relating to sea-affairs, be observed; *intendants of the finances*, who have the direction of the revenues; *intendants of provinces*, who are appointed by the king to take care of the administration of justice, policy, and finances, in the provinces *général*, *intendants of buildings*, of *hospitals*, &c.

INTENDMENT of law, the sense, intention, or true meaning of the law. See COXON.

The judges ought to judge according to the common *intendment* of the law.

INTENDMENT of crimes: in cases of treason, intention proved by circumstances is punishable as if it were put in execution. So likewise, if a person enter the house in the night time, with intent to commit burglary, it is felony; and an assault on the highway, with an intent to commit burglary, is felony, and punishable with transportation, 23 Car. II. c. 1, 7 Geo. II. c. 20.

INTENSIONE, in Law, a writ which lies against him who enters after the death of the tenant in dower, or tenant for life, and holds out him in the reversion, or remainder.

INTENSUM *diatonicum*. See DIATONIC, and GENUS.

INTENT, in Civil Law, signifies to begin or commence an action, or process.

INTENTION, or INTENSION, in Medicine, that judgment, or method, of cure, which a physician forms to himself from a due examination of the symptoms.

INTENTION, in Physics, the increase of the power, or energy, of any quality; as heat, cold, &c. By which it stands opposed to REMISSION, which signifies its decrease, or diminution.

INTENTION, in Metaphysics, denotes an intention of the intellectual faculties with more than ordinary regard; when the mind with earnestness fixes its view on any ideas, considers it on all sides, and will not be satisfied by any solicitation.

The schoolmen also speak of terms of *first* and second intention.

A term of *first* INTENTION is that which signifies a thing, the primary design of men, in establishing words, being to express things, or the ideas they have of things.

A term of *second* INTENTION is that which does not signify a thing, but another term, or sign.

Thus, a tree, a man, &c. are terms of *first* intention; and the terms in rhetoric, grammar, &c. as figure, kind, &c. are terms of *second* intention.

INTENTION, *intento, intentio*, in the *Ancient Myth*, was used to denote the passage of the voice from grave to acute.

INTENTIONAL, *qualitatis*, see **QUALITIES**.

INTER, *inter, & supra*, in *Latin*, words used formerly in appeals to signify that a crime was committed in the twilight, i. e. *inter diem & noctem*, &c. This part of a day has divers other denominations; thus, in some parts of England, they call it *mid-fallow*, corruptly *mid-fall*; and, in the north, *day light's tale*; others say, *between break and break-dawn*.

INTERCALARY, *day*, denotes the odd day inserted in the leap-year. See **BISSEXTILE**.

The word is derived from the *Latin intercalaris*, *of year, calare*, which anciently signified, *to add with a leap year*: an *intercalary day*, among the Romans, signifying a day inserted between two other days; which, for that season, was proclaimed by the priests with a loud voice.

INTERCALATION, see **INTERPOLATION**.

INTERCAPSULARIA, in *Anatomy*, a name, given by some writers to the cavities between the scapula and the vertebra.

INTERCEPT, *axis*, in *Comet Section*, is the same with what is otherwise called the *apogee*.

INTERCESSION, *intercessio*, was used in *ancient Rome*, for the act of a tribune of the people, or other magistrate, by which he inhibited the acts of other magistrates; or even, in case of the tribunes, the decrees of the senate. *Inter* was the solemn word used by the tribunes when they inhibited any decree of the senate, or law proposed to the people. The general law of these *intercessions* was, that any magistrate might inhibit the acts of his equal, or inferior; but the tribunes had the sole prerogative of controlling the acts of every other magistrate, yet could not be controlled themselves by any.

INTERCESSION, *from inter, and cedo, I go between*, a person who prays, supplicates, or intercedes, in behalf of another.

In the Roman law, *intercessor* was the name of an officer, whom the governors of provinces appointed principally to raise taxes, and other duties.

INTERCESSION is also a term heretofore applied to such bishops as, during the vacancy of a see, administered the bishopric, till a successor to the deceased bishop had been elected. See **BISHOP**.

The third council of Carthage calls these *intercessores*.

INTERCIDENT, *puls*, a term used by medical writers to express a sort of pulse, in which between two regular strokes there is perceived a third irregular.

INTERCOLUMNATION, or **INTERCOLUMMATION**, in *Architecture*, signifies the space between two columns. See the plan of *fig. 40*, in *Tab. Architecture*.

Vitruvius calls it *intercolumnium*; which, according to that author, is of five kinds; viz. *pentastyle*, A, one diameter and a half; *hexastyle*, B, two diameters; *octastyle*, C, two and a quarter diameters, which is the most graceful; *diastyle*, D, three diameters; and *areostyle*, E, four diameters; which he explained under their proper heads. **Pentastyle**, &c. The *intercolumniation* or space between the columns in the arcade F, is seven and a half diameters; and the *intercolumniation* wherein there is a space, G, of only one half a diameter, is called coupling columns, an invention attributed to the mollars.

From a measure, some authors have laid down the following proportions: in the *Tuscan order*, the *intercolumniation* is to be four diameters of the body of the column below; in the *Doric*, three; in the *Ionic*, two; in the *Corinthian*, two one quarter; and in the *Composite*, one and a half.

INTERCOMMONING is when the commons of two manors lie together, and the inhabitants of both have, time out of mind, caused their cattle to feed promiscuously in each.

INTERCOSTAL, in *Anatomy*, signifies any thing between two costae, or ribs.

In *Intercostal arteries*, are of four sorts; the *upper*, which commonly comes from the lower side of the subclavian, and divides itself within the four spaces of the upper ribs, sending off under each rib a branch, which runs along the lower edge, and supplies the *intercostal muscles*, and neighbouring parts of the pectora: sometimes this artery comes from the cervicalis, and sometimes from the *aorta descendens*, either by small separate arteries, or by a common trunk, which divides as it runs obliquely up upon the ribs: sometimes it arises from the nearest bronchialis, or from several bronchiales together; the *under* are commonly seven or eight on each side, and sometimes ten, and arise along the back side of the descending *aorta* in pairs, all the way to the diaphragm, and run transversely, towards each side, on the bodies of the vertebrae. Those on the right side pass behind the vena

azygos, and afterwards they all run to the *intercostal muscles*, along the lower edge of the ribs, all the way to the sternum, or near it. They send branches to the pectora, the vertebral muscles, and those muscles which lie on the outside of the ribs, and to the upper portions of the muscles of the abdomen; and they communicate with the capillary and lumbal arteries.

INTERCOSTAL muscles, are either external or internal; and are forty-four in number, one of each sort being between every two ribs.

They arise from the lower edges of each *superior rib*, and are inserted into the upper edges of each *inferior rib*. Their fibres cross one another; those of the external run obliquely from the back part forwards; but those of the internal from the fore part backwards; they are thin and fleshy.—See *Tab. Anat. (Muscl.) fig. 1. n. 43. fig. 2. n. 27.*

These muscles are so many thin fleshy plates, two between every two ribs, an external and an internal, closely joined together with only a thin cellular web between them. The fibres of the external *intercostals* are very oblique near the vertebrae: but this obliquity decreases insensibly as they approach the anterior extremities of the ribs. Their insertions begin at the ligaments, by which the ribs are fastened to the transverse apophyses. They are a little tendinous, and run a small space beyond the edge on the outside of each rib. The fibres of the internal *intercostals* are in general flatter and less oblique than the former; they fill almost entirely the interstices between the cartilaginous portions, and they are covered on the outside by a ligamentary membrane, the fibres of which running in an opposite direction to those of the muscles, have been mistaken for continuations of the external *intercostals*, over which this membrane is also spread, only a little diminished in thickness.

Any portion of the breast of an animal may be boiled so much that the flesh easily parting from the bones, the ribs may be drawn out, without disordering either the muscles or the membranes; but we are not for this reason to conclude, that all the *intercostals* on one side of the breast make but one muscle; because the same reasoning might prove, that all the muscles, which immediately surround the os femoris are but one; since, by a like experiment, they together with the periosteum may be entirely separated from the bone, without breaking their fibres. Winslow's *Anatomy*, p. 239. For the use of these in respiration, see **RESPIRATION**.

INTERCOSTAL nerves, are two nerves so called, because in descending they pass near the roots of the ribs.—They are formed in the brain, by three branches of nerves, two whereof come from the sixth pair, and the third from the fifth. The *intercostal nerves* have a great communication with those of the eighth pair, and send several branches to the breast and lower belly.

Dr. Walcher has given a very minute description of the *intercostal nerves*, and eighth pair. See *Nov. Act. Erud. Lips.* 1734. Feb. & *ibid.* 1736, Sept.

INTERCOSTAL vein, is a vein which arises from the four spaces between the upper ribs, and terminates in the subclavian. See *Tab. Anat. (Vascul.) fig. 1. n. 31. fig. 6. lit. f.* See **ARTERIES**.

INTERCUS, a word used by some medical writers, to express that sort of *Dropy* more usually called an *ANASARCA*.

INTERDICT, a censure inflicted by a pope, or bishop, suspending the priests from their functions, and depriving the people of the use of sacraments, divine service, and Christian burial.

In common law, *interdict* is also used in the same sense as in the canon law; where it is defined to be, *causa ecclesiastica prohibens administrationem divinarum*.

INTERDICT is most properly understood of a general excommunication of a country, or city, as appears by the Decretals. See **EXCOMMUNICATION**.

There is a *local*, and a *personal interdiction*: where these two are joined, the *interdict* is said to be mixed.

This punishment, as well as general excommunications, were but little known till the time of pope Gregory VII. In the year 1169, pope Alexander III. put all England under an *interdict*, forbidding the clergy to perform any part of divine service, except the baptizing of infants, taking confession, and giving absolution to dying penitents.

In excommunicating a prince, all his adherents, that is, his subjects who retain their allegiance, are excommunicated, and the whole country is put under an *interdict*. In the reign of king John, the kingdom of England lay under a *papal interdict* for above six years together: it began A. D. 1208.

In imitation of the popes, the bishops also soon began to *interdict*; and it became a common thing for a city, or town, to be excommunicated for the sake of a single per-

The Use of the preceding Table.

When the *interest* of any sum of money is required for any number of days, look in the tables for the number of

INT

days, and even with that number, under the given rate of *interest*, will be found the *interest* of one pound, for that time, and at that rate; which *interest*, so found, being multiplied by the principal sum, the product answers the question.

EXAMPLE.

What is the *interest* of 462*l.* for 85 days, at 5 per cent. per annum?

In the table, even with 85 days, and under 5 per cent. you find the *interest* of 1*l.* to be .0116438.

Which multiplied by the principal 462*l.* the product will be 5*l.* 7*s.* 2*d.*

N. B. If the principal sum contain shillings and pence, you must reduce them into decimal parts, and multiply accordingly.

When the *interest* of any sum is required for a number of years and days together, as it frequently happens upon paying off a bond or mortgage, add the *interest* of one pound for the years at the end of the foregoing tables, to the *interest* of one pound for the odd days; multiply that by the principal sum, and the product will answer the question.

The following Table is much more compendious; and shews the *interest* of any sum of money, from a million to a pound, for any number of days, at any rate of *interest*.

N ^o	Y.	M.	D.	N ^o	Y.	M.	D.	
1000000	27	14	0	0.99	10000	14	9	
900000	14	5	0	3.79	9000	9	3	
800000	11	15	7	1.49	8000	3	10	
700000	10	17	10	1.38	7000	18	4	
600000	10	17	16	1.28	6000	12	10	
500000	13	19	3	0.49	5000	7	5	
400000	10	15	9	2.91	4000	1	11	
300000	8	21	18	4.16	3000	10	5	
200000	5	14	10	3.40	2000	11	2	
100000	2	19	5	1.70	10000	5	3	
90000	2	11	6	0.90	9000	4	11	
80000	2	19	3	0.90	8000	4	2	
70000	1	15	7	1.59	7000	3	10	
60000	1	14	7	0.21	6000	3	1	
50000	1	10	8	2.81	5000	2	8	
40000	1	10	11	9	1.48	4000	2	2
30000	8	3	10	0.11	3000	1	7	
20000	5	15	10	2.74	2000	1	1	
10000	2	7	11	1.37	1000	0	6	
9000	2	13	1	3.23	900	0	5	
8000	2	18	4	1.10	800	0	5	
7000	1	10	3	6	2.61	700	0	4
6000	1	8	9	2.02	600	0	3	
5000	1	13	11	2.58	500	0	3	
4000	1	10	19	2	0.53	400	0	2
3000	8	4	4	2.41	300	0	2	
2000	5	9	7	0.27	200	0	1	
1000	2	14	9	2.14	100	0	0	

Multiply the sum by the number of days, and then cut off the product thereof by the rate of *interest* per cent. then cut off the two last figures to the right hand, and enter the table with what remains to the left, against which numbers collected, you have the *interest* for the given sum.

EXAMPLE.

What is the *interest* of 100*l.* at 5 per cent. for 365 days?

N^o of days 365 } Then in the table *L. i. d. s.*
Mult. by 100 } against 1000 is 2 14 9 2.14

Product - 36500 800 - 2 3 10 0.11

Mult. by 5 - rate per cent. 20 - 0 1 1 0.60

182500 5 - 0 0 3 1.15

1825 and 5 0 0 0.000

the *interest* required. Ferguson's Treatise, p. 274.

For the method of calculating annuities, see ANNUITIES.

INTEREST, *compound*, is that which is counted both from the principal, and the *simple interest* forborne; called also *interest upon interest*.

Compound interest arises from the principal and its *interest* put together, as that *interest* becomes due. To find this, it is necessary to find the new principal, which is still created by the increase of the growing money, at the several times when the payments of *interest* were due.

Although it be not lawful to lend money at *compound interest*, yet in purchasing annuities, pensions, &c. and taking leases in reversion, it is usual to allow *compound interest* to the purchaser for his ready money; and, therefore, it is very necessary to understand this subject. Let

p, *r*, *n*, and *m*, be as before; and let *a* be equal to *1 + r*, or the principal and *interest* of 1*l.* for any given time, and

any

the side of one of the shoes strikes against and hurts one of the feetlocks. See CUTTING.

INTERJECTION, in *Grammar*, an expression used to denote some sudden motion or passion of the mind: as *ah!* *ho!*

As the greatest part of the expressions used on these occasions are taken from nature alone, the real *interjections* in real languages are monosyllables; and as all nations agree in these natural passions, so do they agree in the signs and indications of them; as of love, mirth, &c. Some deny the *interjections* to be words, or any part of speech; and make them mere natural signs of the motions and passions of the mind, expressed by their natural sounds, several whereof have been in common with us; but as these are passions, and must be repeated in discourse, the *interjection* has a good foundation in nature, and is a necessary part of speech.

Mr. Harris observes, that *interjections* coincide with no part of speech, but are either uttered alone, or else thrown into a sentence, without altering its form, either in syntax or signification; and that they are not so properly parts of speech, as adventitious sounds; certain voices of nature rather than voices of art, expressing those passions and natural emotions, which spontaneously arise in the human soul, upon the view or narration of interesting events. *Hermes*, p. 289.

The Greeks confound their *interjections* with *adverbs*, and the Hebrews confound them with their *adverbs* and *prepositions*; calling them all by their general name *particulae*.

INTERIM, a term borrowed from the Latin, signifying in the mean time. It was first brought into popular use by Charles V. in 1518, in order to compose the disturbances of Germany.

The *interim* of that prince was a kind of ordinance, or regulation, to be observed in the empire, with regard to the articles of religion then controverted, till such time as they should be determined by a council; and therefore was called *interim*.

It was said to have been drawn up by two catholics and a protestant; but as it retained most of the doctrines and ceremonies of the Romish church, though expressed for the most part in the softest words, or in figurative phrases, or in terms of studied ambiguity, excepting that of marriage, which was allowed to priests, and communion, which was administered to the laity under both kinds, most of the protestants rejected it. Those who admitted it were nick-named *Interimists*, or ADIAPHORISTS. Indeed the *interim* equally disgusted the generality of both parties, the protestants and catholics.

Besides this, there were two other *interims* made: the one called the *interim* of Leipzig, the other by the divines of Franconia, who, refusing to accept the two former, made another for themselves.

INTERIOR. See INTERNAL and INTERNE.

INTERIOR figure, angle of. See ANGLE.

INTERIOR polygon. See POLYGON.

INTERIOR talus. See TALUS.

INTERLINEATION, something inserted between two lines. See DICO.

INTERLOCUTORY decree. In a suit of equity, if any matter of fact be strongly controverted, the fact is usually directed to be tried at the bar of the court of king's bench, or at the assizes, upon a feigned issue. If a question of mere law arises in the course of a cause, it is the practice of the court of chancery to refer it to the opinion of the judges of the court of king's bench, upon a case stated for that purpose. In such cases, *interlocutory* decrees or orders are made.

INTERLOCUTORY judgments are such as are given in the middle of a cause, upon some plea, proceeding on default, which is only intermediate, and does not finally determine or complete the suit. But the *interlocutory* judgments most usually spoken of, are those incomplete judgments, whereby the right of the plaintiff is established, but the quantum of damages sustained by him is not ascertained, which is the province of a jury. In such case a writ of *enquiry* issues to the sheriff, who summons a jury, enquires of the damages, and returns to the court the inquisition so taken, whereupon the plaintiff's attorney *sets aside*, and signs final judgment.

INTERLOCUTORY order, that which decides not the cause, but only settles some intervening matter relating to the cause.

As, where an order is made in chancery, for the plaintiff to have an injunction, to quit possession till the hearing of the cause; this order, not being final, is called *interlocutory*.

INTERLOPING, the intercepting, or disturbing, the traffic of a company; or the taking up a new trade or employment, to the prejudice of those who were brought up in it.

INTERLOPERS are properly those, who, without due authority, hinder the trade of a company, or corporation lawfully established, by dealing in the same way.

INTERLUCE, in *Husbandry*, the thinning of a wood, or letting in light between, by lopping or cutting away boughs.

INTERLUDE, an entertainment exhibited on the theatre between the acts of a play; to amuse the spectators while the actors take breath, and fluff their dress; or to give time for changing the scenes and decorations.

In the ancient tragedy, the chorus sang the *interludes*, to show the intervals between the acts.

Interludes, among us, usually consist of songs, dances, feats of activity, concerts of music, &c.

Arthure and Horace give it for a rule, that the *interludes* should consist of songs built on the principal parts of the drama; but since the chorus has been laid down, dancers, buffoons, &c. ordinarily furnish the *interludes*.

INTERLUINIUS morbus, a name by which some authors have called the *EXPLEPSY*, a disease that has been said to be often affected remarkably by the changes of the moon.

INTERMEDIATE is usually understood of the space of time elapsed from any certain point to any other.

In *Chemistry*, those substances are called *intermediate*, by means of which, other substances, incapable of uniting together of themselves, may be united.

INTERMEWING, in *Falconry*, is a hawk's mewing, from the first change of her coat till the turn white.

INTERMITTENT, a thing which ceases its action for some time; which time is called the *interval*.

Thus *FEVERS* which go off, and soon return again, are called *intermittent*, in opposition to those which are always continued.

So a pulse which after so many strokes stops, or loses one in its due time, is called an *intermittent* PULSE.

With regard to this it has been observed, that as often as the stomach is much inflated with wind, the nerves or plexus cardiacus at its orifice must suffer a contraction, which, being continued to the heart, will occasion a twitching; and thus, as it is more or less violent, will produce either only a simple *intermission* of pulse, or a real palpitation of the heart.

INTERNAL angle are all angles made by the sides of any right-lined figure within. See INTERNAL ANGLE.

In a triangle, as KLM (Tab. III. Geometry, fig. 35.) the angles L and M are particularly called *internal* and *opposite*, in respect of the external angle IKM, which is equal to them both.

INTERNAL angle is also applied to the two angles formed between two parallels by a line intersecting those parallels, on each side the intersecting line.

Such are the angles α and γ , and π and ι (Tab. III. Geometry, fig. 36.) formed between the parallels OP and QR, on each side of the intersecting line ST.

The two *internal angles* are always equal to two right angles.

INTERNAL and opposite angle is also applied to the two angles π and α , formed by a line cutting two parallels.

These are respectively equal to Λ and μ , called the *external* and *opposite angles*.

INTERNAL affection, drummatism, ear, mad, orthography, place, sense. See the substantives.

INTERNODIUM, in *Botany*, the space that is between two knots, or joints, of the stalk of a plant; e. gr. of the stalk or straw of wheat, or other corn.

INTERNUS brachialis, rectus major capitis, rectus minor capitis, cubitarius, iliacus, orbiter, pterygideus, vagus. See BRACHIALIS, RECTUS, &c.

INTERNUS mallei, in *Anatomy*, a name given by some authors to one of the muscles of the ear. It is the *musculus internus auris* of Cowper, and is very properly called by Albinus *tensor tympani*, from its use. Spigelius calls it simply the *internus*.

INTEROSSEI manus, the muscles which move the fingers: thus called from their situation, as being contained *inter ossa*, between the spaces of the bones of the metacarpus. Some reckon six of them, and others eight. One half lie between the spaces these bones leave towards the palm of the hand; these are called the *interni* *interossei*, arising from the upper part of the bones of the metacarpus near the carpus; and, being inserted on the internal sides of the first bones of the fingers with the lumbricals, serve as *adductores digitorum*, to bring the fingers to the thumb.

The other half, called *interossei externi*, are contained in the spaces that the bones of the metacarpus leave on the back of the hand; these rise from the upper part of the bones of the metacarpus next the carpus, and are inserted on the external sides of the first bones of the fingers: these serve, as *abductores digitorum*, to draw the fingers from the thumb. See Tab. Anat. (Myol.) fig. 6. n. 23. fig. 7. n. 9. 50.

INTEROSSEI pedis, the muscles which move the toes; in number, six, origin, and insertion, they answer exactly to those of the hand.

INTEROSSEOUS arteries, are two arteries, derived from the cubital artery, where in its course between the brachii of the radius and ulna it reaches the **INTEROSSEOUS ligament**: they are the internal and external. The internal artery runs close to the ligament, till it extends below the pronator teres, where it perforates the ligament, and runs in the convex side of the carpus, and back of the hand, where it communicates with the external **interosseus**, the radial, and the cubital arteries. The external **interosseus** artery pierces the ligament about three fingers breadth below the articulation, and sends off a branch towards the external condyle of the os humeri, under the ulnaris externus, and anconeus minimus, to which it is distributed, as also to the supinator brevis. Having reached the lower extremity of the ulna, it unites with a branch of the internal **interosseus** artery, and is distributed with it on the convex side of the carpus and back of the hand, communicating with the radial artery, and with a branch of the cubital. By these communications this artery forms an irregular arch, from whence branches are sent to the external **interosseus** muscles, and to the external lateral parts of the finger.

INTEROSSEOUS ligaments in the fore-arm, are fixed by one edge along the sharp angle of each ulna, and by the other along that of the radius. They are chiefly made up of two very strong planes of fibres, which cross each other at oblique angles, and leave holes at different distances for the passage of blood-vessels. They serve to tie the two bones closely together, and the two planes serve for the insertion of several muscles. In the supination of the hands they are very tight; but in the pronation they are folded a little lengthways.

INTEROSSEUS, in *Anatomy*, a name given by Spiegelius in his account of the muscles of the foot, to a muscle called by Albinus the *flexor brevis pollicis pedis*, and by Winslow the *flexor and flexor brevis*.

INTERPLEAD, or **ENTERPLEAD**. See **ENTERPLEAD**.

INTERPOLATION, a term used by critics in speaking of ancient writings and manuscripts, in which some spurious additions or alterations have been since made.

To establish or ascertain an **interpolation**, P. Rainart gives us the five following rules. 1. That the piece supposed to be interpolated appear to have all the antiquity it pretends to. 2. That there be good proofs that it has been interpolated. 3. That the supposed interpolations agree to the time of the interpolator. 4. That the interpolations do not touch the foundation of the work; and that they be not too frequent, nor entirely disfigure the piece. 5. That the refutation made, agree perfectly to the rest of the work.

INTERPOLATION, in *Algebra*, is used for the finding an intermediate term of a series, its place in the series being given. This is also called **intercalation**.

The method of doing this is called the **method of interpolation**, or **intercalation**.

When the algebraic equation of the series is given; the term required, whether it be a primary or intermediate term, may be found by the resolution of affected equations; but when this equation is not given, as it often happens, the value of the term sought must be exhibited by a converging series, or by the quadrature of curves. See *Serling*, Method. Different. p. 86, seq. Meyer, in *AD. Petrop.* tom. ii. p. 183, seq.

When the first, second, or other successive differences of the terms of a series become at last equal, the **interpolation** of any term of such a series may be found by Sir Isaac Newton's **DIFFERENTIAL method**.

The method of **interpolation** was first invented by Mr. Briggs, Savilian professor of Geometry at Oxford, and applied by him to the calculation of logarithms. His principles were followed by Reginald and Mouton, in France. Sir Isaac Newton, in lemma 5. lib. iii. *Phil. Princip. Mathem.* gave a most elegant solution of the problem for drawing a curve line through the extremities of any number of given ordinates; and in the subsequent proposition applied to the solution of this problem to that of finding from certain observed places of a comet, the place of it at any given intermediate time. Dr. Waring, who adds, that a solution still more elegant, on some accounts, has been since discovered by Mess. Nicholson and Stirling, has also resolved the same problem and rendered it more general, without having recourse to finding the successive differences. *Phil. Trans.* vol. lxxi. part 2. art. 7.

INTERPOSED stars. See **ATRIC**.

INTERPOSITION, the situation of a body between two others, so as to hide them, or prevent their action.

The eclipse of the sun is occasioned by an **interposition** of the moon between the sun and us; and that of the moon

by the **interposition** of the earth between the sun and moon.

INTERPRETER, a person who explains the thoughts, words, or writings, of some other, which before were unintelligible.

The word **interpreter**, according to Isidore, is composed of the preposition *inter* and *pretor*, signifying a person in the middle betwixt two parties, to make them mutually understand each other's thoughts. Others derive it from *inter* and *pretor*, i. e. *fulgurifer*; q. d. a person who serves as security between two others, who do not understand one another.

There have been great debates about **interpreting** Scripture. The Romanists contend, that it belongs absolutely to the Church; adding, that were she is silent, reason may be consulted; but, where she speaks, reason is to be disregarded. The Protestants generally allow reason to be the sovereign judge, *ex interprete*, though some among them have a strong regard to foods, and others to the authority of the primitive fathers. Lastly, others have recourse to the spirit within every person to **interpret** for them; which is what Bochart calls *arbitrium* *vs. sensum*.

INTERREGNUM, the time during which a throne is vacant, or a kingdom without a head.

In hereditary kingdoms, as England, there are properly no **interregnums**. In elective kingdoms, the **interregnums** are extremely liable to factions and disorders. In Germany, the emperors have lost the greater part of their dominions during the **interregnums**.

INTERREX, a magistrate who governs during an **interregnum**, or in the interval between the death of a monarch and the election or inauguration of his successor.

This magistracy was established in old Rome, and was almost as ancient as the city itself. After the death of Romulus there was an **interregnum** of a year, during which the senators were each **interrex** in their turn, five days a piece.

After the establishment of consuls, and a commonwealth, though there were no kings, yet the name and function of **interrex** were still preserved: for when the magistrates were absent, or when there was any irregularity in their election, or they had abdicated, so that the comitia could not be held, provided they were unwilling to create a dictator, they made an **interrex**, whose office and authority were to last five days; after which they made another. To the **interrex** was delegated all the regal and consular authority, and he performed all their functions. He assembled the senate, held comitia, or courts, and took care the election of magistrates was according to the rules. Indeed, at first it was not the custom of the **interrex** to hold comitia; at least we have no instance of it in the ancient Roman history.

The patricians alone had the right of electing an **interrex**. This office fell with the republic, when the emperors made themselves masters of every thing.

INTERMENT, **INTERMENT**, or **ENTERMENT**, the act of **interring**, i. e. burying, or laying a deceased person in the ground. See **BURIAL**.

The communicants are not to be **interred** in holy, i. e. in consecrated ground. The ancients did not inter their dead; they burnt them, as the Indians do at this day. See **BURNING**.

The Abyssinians in lieu of **interring** their dead. Shut them up in the bodies of trees, dug hollow for this purpose.

Gardeners also **inter**, or earth up, celery, endive, and lettuce, to blanch, or whiten, and make them the tender.

To **inter** wild flocks in ditches, is what Columella calls *deponere semina feribilia*. There are some trees, as willows, olives, &c. which grow very well, by **interring** their trunks, i. e. cutting a trunk, or piece, off at both ends, and planting it in the ground; which is what the Latins call *incunare talia*, *taliter*, &c.

INTERROGATE, a judiciary act, by which a witness or committor deputed to examine him, and who first gives his oath, that he will answer truthfully, is **interrogated**.

INTERROGATION, *Eristici*, a figure of speech, by which the passion of the speaker induces him to ask a way of question, to make its truth more manifest.

The **interrogation** is a kind of apostrophe, which the speaker makes to himself; and it must be owned, that this figure is suited to express most passions and emotions of the mind; it serves also to press and bear down an adversary, and generally adds an uncommon briskness, action, force, and energy, to discourse.

INTERROGATION, in *Grammar*, is a point which serves to distinguish such parts of a discourse, where the author speaks as if he were asking questions. Its form is this (1)

INTER-

INTERROGATORIES, in *Law*, are particular questions demanded of witnesses brought in to be examined in a cause, especially in the court of chancery. And these interrogatories must be exhibited by the parties in suit on each side; which are either direct for the party that produces them, or counter, on behalf of the adverse party; and generally both plaintiff and defendant may exhibit, direct, and counter, or cross interrogatories. They are to be pertinent, and only to the points necessary; and either drawn or perused by counsel, to be signed by them.

INTERRUPTION, in *Matters of Proportion*, denotes the same with *disruption*.

It is noted thus ($;$); and signifies the breaking off of the ratio in the middle of four disjoint or discrete proportionals: as $A:B::C:D$; that is, as A is to B so is C to D . See **RATIO**, **PROPORTION**; &c.

INTERRUPTION is also a figure in *Rhetoric*, wherein a person breaks off his discourse suddenly, to shew some passion.

INTERSCENDENT, in *Algebra*, is applied to quantities, when the exponents of their powers are radical quantities. Thus $Z^{\sqrt{2}}$, $Z^{\sqrt{3}}$, &c. are interscendent quantities. See **FUNCTION**.

INTERSECTION, in *Mathematics*, the cutting of one line or plane, by another; or the point or line wherein two lines, or two planes, cut each other.

The mutual intersection of two planes is a right line. The centre of a circle is in the intersection of two diameters. The central point of a regular or irregular figure of four sides, is the point of intersection of the two diagonals. The equinoxes happen when the sun is in the intersections of the equator and ecliptic.

INTERSEPTUM, a word used by some writers to express the uvula, and by others the septum narium.

INTERSOILING, in *Husbandry*, the laying one kind of soil, or mould, upon another; as clay on sand, sand on earth, &c.

INTERSPERSUM vacuum. See **VACUUM**.

INTERSPINALES celi, in *Anatomy*, the name of five pair of small muscles discovered by Mr. Cowper; and by him so called, from their position along the spine.

They arise from each double process of the spine of the neck, and run from the upper one to the next below, into which they are inserted.

They serve to draw together the vertebrae of the neck; and are more especially proper to this part, as having both their origin and insertion in it.

INTERSPINALES dorsii, in *Anatomy*, a name given by Albinus to certain muscles of the back, not mentioned by the old writers in anatomy, but called by Winslow and other of the modern French writers, *les petits spinaux du dos*; as the *interspinales* lumborum of the same author, are the *spinaux des lombes*.

INTERSPINALES lumborum, in *Anatomy*, a name given by Albinus to some muscles not mentioned by the generality of writers, but called by Winslow the *spinaux des lombes*, or *spinaux lumborum*.

INTERSTELLAR, a word used by some authors to express those parts of the universe that are without, and beyond, the limits of our solar system.

In the *Interstellar* regions are supposed to be several other systems of planets moving round the fixed stars, as the centres of their respective motions; and if it be true, as it is not improbable, that each fixed star is thus a sun to some habitable orb, that move round in the *interstellar* world will be infinitely the greatest part of the universe.

INTERTIES, or *INTERTICES*, in *Architecture*, those small pieces of timber which lie horizontally betwixt the summers, or betwixt them and the fell, or raising plate.

INTERTRANSVERSALES celi, certain muscles between the transverse processes of the vertebrae of the neck; serving for divers motions of the head: of the same size and figure with the *interspinales*, and observed by the same author. See *Phil. Trans.* N° 251. p. 131.

INTERTRANSVERSARIJ dorsii, in *Anatomy*, a name given by Albinus and others of the late anatomists, to certain small muscles of the back, not observed by the old writers on that subject, but called by the French *les petits transverseurs du dos*.

INTERTRANSVERSARIJ lumborum, in *Anatomy*, a name given by Albinus to those muscles of the loins, which Douglas also calls the *intertransversales*, and Winslow, with the other French writers, *transverseurs des lombes*.

INTERTWISTED future. See **SUTURE**.

INTERVAL, the distance or space between two extremes, either in time or place.

The word comes from the Latin *intervalum*, which, according to Isidore, signifies the space *inter solum & murum*, between the ditch and the wall: others note, that the stakes or piles, driven into the ground in the ancient Roman bulwarks, were called *valla*, and the interstices or vacancy between them *intervallo*.

Angle of INTERVAL. See **ANGLE**.

Lucid INTERVAL. See **LUCID**.

INTERVAL, in *Music*, the difference between two sounds, in respect of acute and grave; or that imaginary space terminated with two sounds differing in acuteness or gravity. When two or more sounds are compared in this relation, they are either equal or unequal in the degree of tone: such as are equal are called *unison*, with regard to each other, as having one tone; the other, being at a distance from each other, constitute what we call an *interval* in music; which is properly the distance in tone between two sounds.

Intervals are distinguished into *simple* and *compound*.

Simple INTERVAL is that without parts, or division: such are the octave, and all that are within it; as the second, third, fourth, fifth, sixth, and seventh, with their varieties.

Compound INTERVAL consists of several lesser intervals: such are all those greater than the octave; as the ninth, tenth, eleventh, twelfth, &c. with their varieties. But this distinction, it is to be observed, regards practice only, because there is really no such thing as a least interval. Besides, by a *simple interval* is not meant here the least practised, but such as though it were equal to two or more lesser, which are in use, yet when we would make a sound move so far up or down, we always pass immediately from one of its terms to the other.—What is meant then by a *compound interval*, will be very plain: it is such, whose terms are in practice taken either in immediate succession, or such where the sound is made to rise and fall from the one to the other, by touching some intermediate degree; so that the whole becomes a composition of all the intervals from one extreme to the other.

What we here call a *simple interval*, the ancients called a *diesson*, and the *compound* they called a *system*.

Each of these had its differences; even of the *simple* there are some greater, and others less: but they are always discord; but of the *compound* or *system*, some are concord, others discord. Uniform, it is plain, cannot possibly have any variety: for where there is no difference, as in unisonance, which flows from a relation of equality, it is plain there can be no distinction; unisons therefore must all be concords. But an *interval* depending on a difference of tone, or a relation of inequality, admits of variety; and so the terms of every interval, according to their particular relation or differences, make either concord or discord. Some indeed have restrained the word *concord* to intervals, making it include a difference in tone: but this is precarious; for as the word *concord* signifies an agreement of sounds, it is certainly applicable to unison in the first degree. *Intervals*, it is plain, may differ in magnitude, and there may be an infinite variety, according to the possible degrees of tone; for there is no difference so great or so little, but a greater or a less may possibly be conceived. It is true, with regard to practice, there are limits, which are the greatest and least intervals our ears are judges of, and which may be actually produced by voice or instrument.

The degrees of tone are proportional to the number of vibrations of the sonorous body in a given time, or the velocity of their courses and recourses.—Now these differences in tone constitute, as has been already said, the intervals in music; these therefore must be greater or less, as the differences are; and it is the quantity of these, which is the subject of the mathematical part of music. Those intervals are measured, not in the simple differences, or in arithmetical ratios of the numbers expressing the lengths or vibrations, but in the geometric ratios; so that the same interval depends on the same geometrical ratio, and *vice versa*. It is, however, to be observed, that in comparing the equality of intervals, the ratios expressing them must be all of one species; otherwise this absurdity will follow, that the same two sounds may make different intervals.—To describe the particular methods of measuring the inequality of intervals, would be too tedious: this one rule may be observed, that, to determine in general which of two or more intervals are the greatest, take all the ratios as proper fractions, and the least fraction will be the greatest interval.

The ancients were extremely divided about the manner of measuring intervals.—Pythagoras and his followers measured them by the ratios of numbers. They supposed the differences of gravity and acuteness to depend on the different velocities of the motion which causes sound; and therefore concluded, that they could only be accurately measured by the ratios of those velocities. Which ratios are said to have been first investigated by Pythagoras, on occasion of his passing by a smith's shop, and observing a concordance betwixt the sounds of hammers striking on the anvil.

Aristoxenus opposed this. He thought reason and mathematics had nothing to do in this case, and that sense was the only judge in the dispute; the other being too subtle

lute to be of any use. He therefore determined the octave, fifth, and fourth, which are the most simple concords, by the ear; and by the difference of the fourth and fifth, he found out the tone, which once settled as an interval the ear could judge of, he pretended to measure every interval by various additions, and subtractions made of these mentioned one with another: but this method is inaccurate.

Ptolemy keeps a middle course betwixt the two: he finds fault with the one for despoiling reason, and with the other for excluding sense; and shews how these two may mutually assist each other in this matter. *Malcolm.*

Intervals are founded on certain ratios or proportions: expressible in numbers, which may all be analysed into the prime-numbers 2, 3, and 5. And all intervals may be found from the octave, fifth and third major, which respectively correspond to these numbers. These are the musicians elements, from the various combinations of which all the agreeable variety of relations of sounds results.

This is the modern system, and a late author assures us, it may be looked on as the standard of truth: and that every interval that occurs in music is good or bad, as it approaches to, or deviates from what it ought to be, on these principles. He observes, that the doctrine of some of the ancients seems different. Ptolemy for instance, introduces not only the primes 2, 3, 4, 5, but also 7 and 11, &c. Nay, he seems to think all fourths good, provided their component intervals may be expressed by super-particular ratios. But these are justly exploded conceits; and it seems not improbable that the contradictions of different numerical hypotheses, even in the age of Aristoxenus, and their inconsistency with experience, might lead him to reject numbers altogether.—*Dr. Pepusch ap. Phil. Trans. N° 451, p. 267, 268.*

Mr. Euler defines an interval, the measure of the difference of an acute and grave sound. *Tentam. Nov. Theor. Music. p. 73, and p. 103.*

Suppose three sounds a, b, c , of which c is the acute, a the most grave, and b the intermediate sound. From the preceding definition it appears, that the interval between the sounds a and c , is the aggregate of the intervals between a and b , and between b and c . Therefore if the interval between a and b , be equal to that between b and c , which happens when $a : b :: b : c$, the interval between a to c will be double the interval a to b , or b to c . This being considered, it will appear that intervals ought to be expressed by the measures of the ratios, constituting the sounds forming those intervals. But ratios are measured by the logarithms of fractions, the numerators of which denote the acute sounds, and the denominators the grave. Hence the interval between the sounds a and b , will be expressed by the logarithm of the fraction $\frac{b}{a}$, which is usually denoted by I_{ab} , or, which

comes to the same $Ib - Ia$. The interval therefore of equal sounds, a to a , will be null, as $Ia - Ia = 0$. The interval called an octave or diapason, will be expressed by the logarithm of 2; and the interval of the fifth or diapente will be $I3 - I2$. From whence it appears, that these intervals are incommensurable; so that no interval, however small, can be an aliquot part, both of the octave and fifth. The like may be said of the intervals $I4$ and $I5$, and others whose logarithms are dissimilar. But intervals expounded by logarithms of numbers, which are powers of the same root, may be compared.—Thus, the interval of the sounds $27 : 8$, will be to the interval of the sounds $9 : 4$, as 3 is to 2: For $I\frac{27}{8} = 3I\frac{3}{2}$, and $3I\frac{3}{2} = 2I\frac{9}{4}$. *Euler, ibid. p. 74.*

But though the logarithms of numbers, which are not powers of the same root, be incommensurable, yet an approximating ratio of such may be found. Thus the measure of the octave is $I2 = 0.3010300$, and the measure of the fifth is $I3 - I2 = 0.1760913$. Hence the interval of the octave will be to that of the fifth, nearly as 3010300 to 1760913; which ratio being reduced to smaller terms, in the method explained under the head RATIO, will give us these simpler expressions for the ratio of the octave and fifth, 2:1, 3:2, 5:3, 7:4, 12:7, 17:10, 29:17, 41:24, 53:31, which last is very near the truth. *Euler, ibid. p. 75.*

In like manner intervals may be divided into any number of equal parts; for this purpose we need only divide the logarithm of the proposed interval into the same number

of parts, and then find its correspondent numbers by the tables. The ratio of the number so found, to unity, will give the required ratio of the divided interval to its proposed part. Thus let the third part of an octave be required; its logarithm will be $= 0.1003433 = \frac{1}{12}$. The ratio corresponding nearly to this will be 63:50, or less accurately, 29:23, or 5:4, which last expresses the third major; and this is the best knowing taken for the third part of an octave, and seems to be such on our harpsichords and organs, where from C to E is a third; from E to G another, and from G to A[♯] or A[♮] to another third. But the more intelligent know, that G $\sharp$ and A[♮] ought not to be reputed the same sound, since they differ by a diesis enharmonica, which is nearly equal to two commas.

Mr. Euler has inserted a table of intervals in his *Tentamen Novæ Theoriæ Musicæ*; he supposes the logarithm or measure of the octave to be 1.000000, whence the logarithm of the fifth will be 0.584962, and the logarithm of the third major will be 0.321928; from these the measures of all other intervals may be found. But as it has been customary for musicians to measure their intervals by commas, we shall here insert a table of intervals with their measures in commas; where we suppose the logarithm or measure of the comma $\frac{1}{12}$ to be 1.000000; hence the logarithm of the octave $\frac{1}{2}$ will be 55.79763, that of the fifth 32.63952, and lastly that of the third major 17.66282. From these all the other intervals may be found in the manner expressed in the table; where the first column shews the names of the several intervals; the second, the proportions of sounds forming these intervals; the third, the composition of those proportions from the primes 2, 3, and 5. The smaller figures marked above, and somewhat to the right of the larger, indicate the power to which the number expressed by the larger figures is raised. Thus $\frac{2^{17}}{5^3}$ shews that the seventeenth

power of two multiplied by 3, and divided by the eighth power of 5, will produce $\frac{2^{17}}{5^3}$ in the second column, and that this is the proportion expressing the interval called *sextaton* in the first column. The fourth column of the table contains some simple signs of some of the intervals, as b for *hyperbole*, d for *diesis*, &c. and the fifth column shews how the intervals arise from others: thus over-agut semitone major, I find in the fourth column S, which is here only an arbitrary mark for this semitone; and in the fifth column I find $I4 - I3 = IV - III$, which signifies that the semitone major is equal to the sum of the semitone minor and diesis, or to the difference between the fourth and third major. Observe, that the comma is marked by a dot ($\cdot$); when this is placed over the letter or other symbol, it signifies that the interval is supposed to be heightened by a comma; and on the contrary, when the point is placed below, it signifies that the interval must be diminished by a comma. Thus $I = T$ signifies that the tone-minor increased by a comma is equal to a tone major, and vice versa, $T = I$ shews that the tone-major diminished by a comma is equal to the tone-minor. The signs $+$, $-$, $=$, are here taken in the same sense as in algebra, to signify addition, subtraction, and equality. So likewise the dot placed between two numbers, or between a number and the symbol of an interval, signifies that the interval is to be multiplied by the number. Thus 2. IV shews that the fourth is doubled; and thus $7^{\circ} = VI + 8 = 2. IV = VIII - I$, shews that the lesser flat seventh is equal to the sixth major and semitone-major, or also to two fourths, or to the octave when the tone-major has been taken from it. Lastly, the sixth column of the table shews the measures, or logarithms of the ratios in the second column. These are not the common logarithms of the tables where 1.000000 is the logarithm of 10.81. But here 1.00000 is assumed as the logarithm of $\frac{1}{12}$, or of the comma, as before mentioned. These logarithms are easily derived from the columns of the larger tables of Vlacq, or Briggs, &c. thus the logarithm of 2, or the octave $= 0.3010299$; of the fifth $= 0.1760913$, or of the fifth $= 0.1760913$; of the third of 2, or of the third major $= 0.321928$; and these logarithms being severally divided by the logarithm of $\frac{1}{12}$, or of the comma $= 0.0055399$, the quotients will give the number of commas in an octave $= 55.79763$; in a fifth $= 32.63952$; and in a third major $= 17.66282$. Hence all the rest may be found by addition and subtraction only. Here follows the Table.

A TABLE of the Musical Intervals, with their Measures.

Names of the Intervals.	Proportions of the Intervals, from 2, 3, and 5.	Composition of the proportions from 2, 3, and 5.	Simple Signs.	Complex Signs to show the Composition of Intervals.	Measures by Commas.
Epichorton — — — — —	$\frac{3932116}{390625}$	$\frac{2^7 3^3}{5^8}$		$f = 2d - d = 3d - S$	0.53222
Diafchisma — — — — —	$\frac{2048}{2025}$	$\frac{2^8 5^2}{3^4}$			0.90917
Comma — — — — —	$\frac{81}{80}$	$\frac{3^4}{2^7}$		T - r	1.00000
Comma of Pythagoras — — — — —	$\frac{531441}{524288}$	$\frac{3^{11}}{2^{19}}$		6 T - VIII	1.09083
Hypersicche — — — — —	$\frac{3125}{3072}$	$\frac{5^5}{2^{10} 3}$	b	$t - d = S - 2d$	1.37695

				$VIII = VII + IV$	55.79763

The limma, apotome, trihemitone, ditonus, femiditonus, and tritonus, mentioned in this table, by the names of limma, apotome, &c. of the Greek scale, are such as are either mentioned by the ancients, or at least occur in their scale, where fourths are divided into two tones and a limma, and where the octave consisted of five tones and two limmas.

The term *redundant*, in the table, is applied to such intervals as exceed the truth by a comma; and such as fall short of the truth by a like quantity, are called *deficient*. Intervals that exceed true diatonic intervals, by a semi-tone-minor, are said to be *superfluous*; and those which fall short by the same quantity are said to be *diminished*. Where an interval exceeds a true diatonic interval by the quantity of two semitones minor, we have called it an *extreme superfluous interval*. And if it falls short by the same quantity the appellation of *extreme diminished interval* is given it. Thus, if from A to D ascending be a true fourth, and from D to A a true fifth, then, if D be supposed raised by a comma, from A to D will be a redundant fourth, and from D to A a deficient fifth. From A to D will be a superfluous fourth, and from D to A will be a diminished fifth. In like manner, from A to D^b will be a diminished fourth; and from D^b to A a superfluous fifth. From A to D^{##} (D double sharp) will be an extreme superfluous fourth, and from A to D^{##} (D double flat) will be an extreme diminished fourth. In like manner from D^{##} to A will be an extreme diminished and from D^b to A, an extreme superfluous fifth. Such intervals are not to be met with in the practice of music; but if the division of the octave into 31 parts were once established, as it ought for the perfection of music, such intervals as these here mentioned will necessarily occur in the scale. Vide Phil. Trans. N^o 481. p. 273, 274. See GENUS.

This table, among other uses, will facilitate the examination of any proposed scale, or interval. Suppose, for instance, it were required to examine some of Ptolemy's divisions of the fourth, as his diatonic molle, which he makes $\frac{3}{2} + \frac{1}{3} + \frac{1}{4} + \frac{1}{5}$. Take the logarithm of $\frac{1}{2}$ from the common tables and divide it by the logarithm of $\frac{3}{2}$, the quotient will be 10.75, which gives the measure or number of commas, and its parts contained in an interval expressed by $\frac{1}{2}$. Look for the nearest measure of intervals to 10.75 in the table, it will be found to be 10.3923, which answers to the interval of two semitones major, or of the diminished third, as practitioners call it. But Ptolemy's exceeds this by 0.36, or about $\frac{1}{4}$ of a comma. The next interval in Ptolemy's division is $\frac{4}{3}$, which is a true tone-minor. The third is $\frac{5}{4}$, which will be found to be 3.93 commas, that is a semi-tone minor and 0.64 of a comma, or a semi-tone

minor redundant by near $\frac{1}{2}$ of a comma. But this is much out of tune. In the common, and in Huygens's temperaments, the semitone minor is increased only by about $\frac{1}{2}$ of a comma. Vide Ptolemy's Harmon. p. 92. apud Wallis Opera, tom. v.

Continuous Intervals, in Music. Discords are distinguished into *continuous* and *inconcinuous intervals*: the *continuous* are such as are fit for music, next to, and in combination with concords; being neither very agreeable nor disagreeable in themselves; but having a good effect, as by their opposition they lighten the more essential principles of pleasure; or as by their mixture and combination with them, they produce a variety necessary to our being better pleased.

The other discords that are never used in music, are called *inconcinuous*.

Interval, *Diminished*, in Music, is a defective interval or an interval which is short of its just quantity by a lesser semitone. Thus from Cⁿ to E being a third minor, if E be lowered by a semi-tone minor, we shall have E^b, and then from Cⁿ to E^b is called a *diminished third*, in the language of practical musicians, and occurs frequently in their works. But strictly speaking, in this case, the note E must be lowered more than a semi-tone minor.

Interval, *Harmonical*, in Music, is an interval, or difference of two sounds which are agreeable to the ear, whether in consonance or succession.

Harmonical Intervals, therefore, are the same with *concord*. They are thus called, as being the only essential ingredients of harmony.

Interval, in the New Method of Husbandry, denote the wide spaces, commonly about five feet, which are left between any two of the double, treble or quadruple rows. See HUSBANDRY.

Intervals, in the Military Art, are the spaces left between each regiment in camp, and likewise between each tent.

INTERVERTEBRALES Musculi, are a set of muscles, arising from the body of one vertebra laterally, and ascending, after an oblique progress, into the back part of the next vertebra, immediately above it. They draw the vertebra nearer to one another, and a little to one side.

INTESTATE, a person who dies without making a will. An *heir ab intestate*, is a person who inherits an estate by some other right, than that of will or testament.

Henceforth, those who died *intestate*, were held infamous, and accursed; in regard, by the canons of several councils, every person was enjoined to bequeath a part of his estate (and Matthew Paris says it was at least one tenth part) to the church, for the safety of his soul; which a person who neglected to make a will, and to leave this legacy to the church, was judged to have

abandoned.—Several councils took on them to command the priests to solicit dying persons to be charitable to the church; and this they did so earnestly, that abolition and the vaticum were denied to those whom they could not prevail on; so that they made no difference between these *infantes* and self-murders; and they were alike denied Christian burial.—Du-Cange adds, that all who died without abolition, without receiving the vaticum, and without leaving alms to the church (even though they died suddenly), had their effects seized, and confiscated to the use of the church, bishop, &c.

In the English law there are two kinds of *infantes*: the one *de facto*, which are those who make no will at all; the other *de jure*, called also *quasi-infantes*, which are those who make a will; but such an one as is null and void, either from the executors refusing to act, or from some other cause: in which case they are judged to die as *infantes*, *quasi-infantes*.

And the 22 and 23 Car. II. c. 10. commonly called the statute of distribution, appoints a distribution of *infantes'* estates, after debts and funeral expenses are paid, among the wife and children of the deceased; or for want of such, among the next of kin, &c. and the act of parliament doth immediately upon the death of the *infante* vest an interest in the persons entitled to that if any one dies before the distribution, though within the year, his share shall go to his executors and administrators; and not to the survivors or next of kin to the *infante*. 1 Lil. Abr. 487. See ADMINISTRATION. The brothers and sisters of the *infante* shall have equal shares with the mother. 1 Jac. II. c. 17. See CUSTOM of LONDON.

By the same statute it is enacted, that one third part of the surplusage of the estate of any person dying *infante*, shall be distributed to his wife, and the residue amongst his children by equal portions, or amongst such persons as legally represent his children, in case any of them be then dead, excepting such child or children (not being heir at law) who shall have any estate by the settlement of the *infante*, or shall be advanced by the *infante* in his life-time, by portion or portions equal to the share which shall by such distribution be allotted to the other children; and in case their portions have not been equal, they shall be made so as nearly as possible out of the said surplusage. But the heir at law is to have an equal part in the distribution with the rest of the children, without any consideration of the value of the land which he hath by descent or otherwise from the *infante*. In case there be no children nor legal representatives, one moiety of the said estate shall be allotted to the wife of the *infante*, and the residue distributed equally to every of the next kindred of the *infante*, who are in equal degree, and those who legally represent them; provided that there be no representations admitted among collateral, after brothers and sisters children: and if there be no wife, the said estate shall be wholly distributed in equal shares among the children; or if there be no child, to the next of kindred in equal degree, and their legal representatives. But no such distribution of the goods of an *infante* should be made till after one year be fully expired after his death, and those to whom distribution is made, are required to give bonds with sufficient sureties, to refund in case of debt.

INTESTINA, in the *Linnaean System*, a genus of worms; the characters of which are that they are simple naked animals without limbs: some are pierced with a lateral hole or a kind of pore; and others are imperforated and have no lateral pore. The subordinate genera of this division of worms are the *gordius*, *ascaris*, *lumbricus*, *fasciola*, *sparganum*, *hirudo*, and *myxine*, comprehending twenty-four distinct species described by LINNÆUS. *Syst. Nat. tom. I. pars 2. p. 1675. &c. Ed. 1767.*

INTESTINE motion. See MOTION.

INTESTINE war. See WAR.

INTESTINES, INTESTINA, in anatomy, the guts or bowels; those hollow membranous, cylindrical parts, extended from the right orifice of the stomach to the anus; by which the chyle is conveyed to the lacteals, and the excrements are voided.

The *intestines* seem to be nothing but a continuation of the stomach; as consisting of the same number of coats, and fabricated in the same manner; they are protended with various circumvolutions and inflexions to the anus, through which they discharge the excrementitious parts of their contents out of the body.

They are, when separated from the mesentery, to which they are all along connected, of a very great length; ordinarily about six or seven times as long as the person's height whole they were. And though they seem to be but one continued channel or fistula, yet because in several parts their magnitude, figure, and thickness, are different, they are in general divided into the *thick* and *small*; and these are again each of them subdivided into

three; the three small are called *duodenum*, *jejunum*, and *ileum*; and the thick, *cæcum*, *cælon*, and *rectum*. They have all of them, in common, a kind of vermicular motion, which, beginning at the stomach, is propagated downwards, and is called the *peristaltic motion*. To facilitate that, they are generally lubricated with a great deal of fat, especially the thick ones, whose surface being somewhat more uneven, and the contents less fluid than those of the small, they need somewhat more to make them slide easy.—See *Tab. Anas. (Splanchn.) Fig. 3. lit. n. Fig. 6. lit. a, b, c, Fig. 7. d, e.* See PERISTALTIC.

INTESTINA tenuia, the small guts.—The first is called *duodenum*, and reaches from the right orifice of the stomach, as far as the vertebra of the back on the left-side, where, at the first angle made by the *intestines*, it ends; which is about twelve inches; from which measure it seems to have taken its name. This measure, however, is far from being very exact, as being much too largely computed. Into this gut the gall-duct and pancreatic duct empty themselves, and their several liquors here mix with the chyle. See DUODENUM.

The next *intestine* is the *jejunum*, so called, because it is generally found more empty than the rest; which may be occasioned, partly by the fluidity of the chyle, which is greater in this *intestine* than in any of those that follow it; and partly by its capacity, being somewhat larger than that of the *duodenum*, and therefore it gives a freer passage; and perhaps also the irritation of this gut through the acrimony of the bile, which is discharged into the *intestine* a little before the beginning of this gut, may contribute something towards accelerating the passage of the contents. However, it may seem sufficient, that through the great number of lacteals, with which this gut abounds more than any other, the descent of the contents, which are here deprived of their most fluid parts, should in the rest be more sluggish, by reason of their great consistence.—This *intestine* is allowed to possess almost the whole umbilical region, and its length is generally computed to be about twelve or thirteen hands breadth.

The *ileum*, which is the third *intestine*, is situated below the navel, and fills the ilia with numerous folds and convolutions.—It is much the longest of all the *intestines*, being esteemed to be one-and-twenty hands long; but these estimates are somewhat arbitrary, because it is not exactly settled among anatomists, where the *jejunum* ends, or the *ileum* begins; neither is it easy or necessary to do it.—In both this and the preceding *intestine*, the inner tunic is much corrugated, the loose folds of which have been thought to do, in some measure, the office of valves, and have therefore by authors been called *valvule conniventes*, which are framed, as in the stomach, only by the inner coat being larger than the outward.

INTESTINA crassa, the thick guts.—The first is called the *cæcum*, which has a lateral insertion into the upper end of the colon; and is not perforated at its other extremity, but hangs to it like the finger of a glove; and is about three or four inches long. The true use of this part is not yet determined, and some late anatomists have thought, that the name likewise is mistaken, not allowing this to be the *cæcum* of the ancients, which they imagined to be that thick globous part of the colon, which is immediately appended to the ileum; and therefore they have given this part the name of *appendix vermiformis*. This *cæcum*, or appendix, is proportionally bigger in infants than in adults, and in many other animals even smaller than in men; and is, at the unperforated extremity, slightly connected to the right kidney.

The next of the thick *intestines* is the colon, which is much the largest and most capacious of them all. It has a great many cellular, or, as it were, distinct cavities, framed by a coarctation of the gut by two ligaments, or bundles of membranous fleshy fibres, about half a finger broad, each running on either side the gut opposite to each other, the whole length of it; and as it were girding it in at certain distances, thereby making it resemble a glass incorporator, used in mixing oil and vinegar.—The last of the *intestines* is the *rectum*, which reaches from the os sacrum to the anus, and is plain, without cells. It is fast tied to the os sacrum and os coccygis, by means of the peritonæum, and in men to the neck of the bladder of urine, in women to the vagina uteri, to which it is so strongly connected by a membranous substance, that the substance of the vagina and *intestine* are hardly distinguishable from one another. The length of this gut is ordinarily about a hand's breadth and a half, and its capacity about the thickness of three fingers; its lower end, the anus, is furnished with three muscles, viz. the *sphincter ani*, and two *levatori ani*, which see.

There are also in the *intestines* a great number of glands, which in the *intestina tenuia*, are gathered together in heaps,

heaps, as it were like bunches of grapes. In these *intestines* they are very small, and were it not for their coarctations, would be scarce visible. But in the *intestina crassa* they are much larger, not gathered like the others, but dispersed, and though very numerous, they come under the denomination of *saltatory glands*. The glands discharge a liquor into the *intestines*, whether ordinarily for any thing more than the lubrication of the *intestines*, and diluting their contents, is not certain; though through these seems the greatest part of the discharge to be made, which, either upon extraordinary fluxes, or upon the administration of cathartics, we have frequent occasions to observe.

The *intestines*, in general, are furnished with blood from the mesenteric arteries, which is returned by the mesenteric veins; but the duodenum receives a branch of an artery from the celiac, which is called the *duodeno*; to which answers a vein of the same name that likewise returns the blood to the porta; the rectum receives others, which are called *hemorrhoids*; the internal from the inferior mesenteric, and the external from the hypogastric, with veins corresponding of the same name, that also go to the porta. These vessels spread the *intestines* with abundance of ramifications, and are frequently diversified in several subjects of the same species; much less are they to be depended upon for a uniform appearance in animals of different kinds. The nerves of the *intestines* come some of them from those of the stomach, and some from the great mesenteric plexus, which distributes branches to all the *intestines*. The remaining vessels of the *intestines* are the lymphatics and venæ lactæ.

The use of the smaller guts is to promote the formation of the chyle, to perfect its secretions, and to propel the remaining faeces to the larger. The office of the larger guts is to receive and collect the matter of the faeces, and at a proper time to expel it. See Miscellaneous Remarks on the *Intestines*, by Dr. Monro. Edinb. Ess. vol. IV. art. 12.

INTESTINE, Wounds of. When a large wound is made in the cavity of the abdomen which not only lets out the *intestines*, but also divides some part of them, the wounded part of the *intestines* is always to be stitched up before they are returned, by which means the wound heals the more readily; and the discharge of the chyle and faeces into the cavity of the abdomen is prevented, from which dangerous symptoms would otherwise have ensued. And although wounds of the *intestines*, especially of the small guts, admit of little or no hopes of a cure; yet as the great guts sometimes admit of the future with advantage, it is better to use a doubtful remedy than none. Small wounds of the *intestines*, however, or such as do not exceed the diameter of a goose-quill, are by no means to be stitched, but left to nature; by which means there is much greater hope of faeces than from irritating them with the future; but large wounds of the *intestines* though they seldom admit of cure, yet this is always to be attempted by means of the glove's future, before the *intestine* is returned. To perform this, you are to be provided with a small needle threaded with silk; an assistant should take hold of one part of the gut by a fine piece of lincen will assist, while the surgeon should hold the other part in his left-hand, and sew up the whole wound after the glove's manner, leaving very small spaces, not more than the twelfth of an inch between each of the stitches. The last stitch in this operation must be fastened with a knot, but the other end must hang about a foot out of the abdomen, by means of which the silk may be drawn out when the *intestine* is healed. After this is performed the wound of the abdomen is next to be taken care of, and stitched up, keeping the lower or depending part of the wound open with a tent, till all the preternatural fluids are discharged out of the cavity of the abdomen, and till the union of the wound in the *intestine* shall give leave to draw away the silk with which the future was performed on it.

As the modern surgeons, however, have found that few are saved who have received any large wound in the *intestines*, and that in those few who do recover, the wounded parts from the fineness of the coat of the gut do not properly unite, but rather adhere to the inner part of the peritonæum, or to the omentum, or to some other of the *intestines*, they rather choose now to let alone the operation of the future of the gut, and substitute a gentler method of cure. They pass a waxed thread through a fine needle, and with this they *listen* the wounded part of the *intestine* to the internal orifice of the wound in the abdomen. The thread that in this case hangs out of the abdomen, is to be firmly fixed by the application of sticking plasters to the wound, that the *intestine* cannot recede from that part to which it is fastened, nor can it evacuate any of its contents into the cavity of the abdomen. When this operation is well performed, the *in-*

testine easily adheres to the internal part of the abdomen, and the patient suffers infinitely less pain and hazard than from the former way of making the future. The same method of cure also is the proper one for wounds of the stomach, when they are within the reach of the hand, and it is sometimes crowned with success. Heister's Surgery, p. 56. See GASTROGRAPHY.

Left of substance in the INTESTINE. Where any part of the *intestines* is carried away, the case is plainly desperate, and it is indeed wonderful that persons thus wounded have not all died upon the spot, or in the operation of making the future, till some of the late eminent surgeons observed that the lips of the *intestines* so wounded, would sometimes unexpectedly adhere to the wound in the abdomen, and took this hint from nature towards a cure in such desperate cases. Whenever a surgeon therefore is called in a case of this kind, after diligently examining the state of the upper part of the *intestine* which has suffered the loss of substance, he should stitch it to the external wound; for by this means the patient may not only be saved from instant death, but there have been instances where the wounded *intestine* has been so far healed that the faeces which used to be voided by the anus, have been voided by the wound in the abdomen. And this though from the necessity of wearing a tin or silver pipe, or keeping cloths constantly upon the part to receive the excrement, may seem to be very troublesome; yet it is surely far better to part with one of the conveniences of life than to part with life itself; beside the excrements that are voided by this passage, are not so offensive in smell as those voided per anum.

The same method of cure may conveniently also be put in practice, where any part of the *intestine* is mortified, by having been thrust out of the abdomen; for in this case if you tie up the mesenteric arteries, the corrupted or mortified part of the *intestine* may be cut off, and the remaining sound part made to adhere to the wound of the abdomen. And it is surely better to try this method and save it if it be only a few by it, than to leave all in this unhappy situation to perish without help. Heister, p. 62.

We have instances of mortified pieces of the *intestines* in the *HERNIA* cut away, and a cure made by keeping the extremities of the gut neat to each other, and near to the rings of the muscles, with a stitch through the mesentery. The ends of the *intestines* grew to the peritonæum, new flesh was extended along this membrane, and joined the extremities together. The folded part of the gut is always strengthened, and therefore those who are cured in this case ought to guard against too full meals and indigestion. See Memoires de l'Academie de Chirurgie, tom. I.

INTESTINES, Falling out of the. See HERNIA.

INTESTINES, Inflammation of the. See ILIAC PASSION.

INTESTINES of fish. The guts in fishes are very different in the several kinds in length, proportion, and figure; in some fish the *intestine* is straight and simple, and is carried directly from the stomach to the anus, as in the conger, *lyngnathus* and *petromyzon*; in others it is only once returned upward, as in the cyprini, salmon, perch, and many others. In others it is variously contorted and revolved, in the same manner as in land animals; we have instances of this in the *sparus*, dolphin, mullet, and sword-fish.

In length there are many very eminent differences. In the *petromyzus*, &c. the whole *intestinal* canal is not so long as the body of the fish. In the cyprini of many kinds it is about the same length with the body of the fish; and in others it is greatly longer, as in the *spari*, mullet, &c.

INTESTINAL FEVER. See FEVER.

INTESTINAL SPINDLER. In *Anatomy*, a name given by Winslow to a muscle of the anus, called by Albinus *spindler internus ani*. It is called by Riola, and others, *spindler cutaneus*, and *spindler superficialis*.

INTESTINUM CECUM. The fish kinds have in general a great number of these *cæca*; they are called by the ichthyologists *intestinales cæca*, and *appendices pycni*. They are always placed about the pylorus, and the beginning of the *intestinal* canal, and seem by their number and appearance to contribute not a little to the digestion of food. They are very different in the several kinds of fish, in number, figure, and proportion. In some fish there are none of them. The catenaceous fishes in general are without them, and the cartilaginous of many kinds also want them. In the ammodytes or sand-eel there is only one *cæcum*, and this seems the only fish that has it single. In many of the pleuronecti they are two in number, and very short. The perch, *spari*, &c. have five, six, or seven of them, and all considerably large ones. In some fish there are eight, ten, or twelve of them, as in the cotti, and some of the ligyri. In the herring and anchovy

there are seventeen or eighteen of them. Some, but not many fish, have twenty or more, not arriving at thirty. The gadi, and some other fish have thirty; and the coronges and salmon, at least sixty of them. The clupea or thrills of authors has at least eighty of them; and the sword-fish, the tunny, the mackerel, and many others have more than an hundred of them, or have them indeed without number. Their differences in figure are also very great. In some fish they are long and narrow, as in the salmon, gadi, and clupea. In others, they are very short and thick as in the pleuronecti, and omerus. In the greatest part of fishes they are much smaller than the rest of the guts; but in the mullet and sand-eel, they are nearly as large as the intestines itself. It is remarkable, that their appendices to the pylorus, or *intestini*, are not only found in fishes, but in some insects. Dr. Tyson found three or four of them in that species of insect called the *blatta*.

INTIRE Tenacity. See ENTIRE Tenacity.

INTRADA, in the Italian *Blasie*, is used to denote an entry, and is much the same as *prælo* or *statura*.

INTRANSITIVE Part, in Grammar, such whose action does not (*transire*) pass on an object, or subject. See VERB Nomin.

INTRENCHMENT, in the Art of War, all sorts of works made to fortify a post against an enemy. See RENTRENCHMENT.

They usually consist only of a bank of earth and a ditch, and are of two sorts; such as the trenches carried on in a siege, where the bank is between the ditch and the enemy's town; and where the earth is thrown up against the town; and such as serve to inclose a town or camp, secure a pass, cover the entrance into a country or other place, &c. In these the ditch is between the bank and the enemy. The first sort are usually called TRENCHES or APPROACHES; and the second are generally called LINES.

It was a maxim amongst the Romans, that even in their most hasty marches they *intrenched* every night.

INTRIGUE, or INTERLUQUE, an enlanguage of events, or circumstances occurring in an affair, and perplexing the persons concerned in it.

The word is French, *intrigue*, formed from the Latin *intricare*; which, according to Nonius, comes from *triste*, entanglement; and that from the Greek *τρίτος*, hairs; *quod polli gallicantur vocantur & impeditur capilli*. Which conjecture is adopted by Tripaud, who will have the word *intrigue* to be primarily and properly understood of chickens, which have the feet entangled in hair; and to be derived from the Greek *ειν*, and *σπιν*, hairs.

INTRIGUE is more particularly used to signify the plot of a play, or romance; or that point wherein the principal characters are the most embarrassed, through the artifice and opposition of certain persons, or the unfortunate falling out of certain accidents and circumstances. In a tragedy, comedy, or epic poem, there are always two designs; the first and principal is that of the hero of the piece; the second contains the designs of all those who oppose him. These opposite causes produce opposite effects, to wit, the efforts of the hero for the execution of his design, and the efforts of those who thwart it. As those causes and designs are the beginning of the action, so those efforts are in the middle, and there form a knot or difficulty, which we call an *intrigue*, that makes the greatest part of the poem. It lasts as long as the mind of the reader or hearer is suspended about the event of those opposite efforts; the solution or catastrophe commences when the knot begins to unravel, and the difficulties and doubts begin to clear up.

The *intrigue* or plot of the Iliad is two fold, the first comprehends the three days fighting in Achilles's absence, and consists, on the one side, in the resistance of Agamemnon and the Greeks, and on the other, in the inexorable temper of Achilles. The death of Patroclus unravels this *intrigue*, and makes the beginning of a second. Achilles, resolves to be revenged, but Hector opposes his design; and this forms the second *intrigue*, which is the last day's battle.

In the *Æneid* there are also two *intrigues*: the first is taken up in the voyage and landing of *Æneas* in Italy; the second in his establishment there. The opposition he met with from Juno, in both those undertakings, forms the *intrigue*.

As to the choice of the *intrigue*, and the manner of unravelling it, it is certain they ought both to spring naturally from the ground and subject of the poem.—Bosiu gives us three manners of forming the *intrigue* of a poem: the first is that already mentioned; the second is taken from the fable, and design of the poet; in the third, the *intrigue* is so laid, as that the solution follows from it of course.

VOL. II. N° 127.

INTRIGUE in common language is used to denote a plot; a private transaction in which several parties are engaged, and usually an affair of love. Johnson.

INTRINSIC, a term applied to the inner, real, and genuine values, properties, &c. of any thing; in opposition to their *extrinsic*, apparent, or popular values, &c. See EXTRINSIC.

INTRITA, a name given by some authors to the *malitia*, a liquid bitumen used by the ancients instead of mortar in building.

INTRODUCTION, in Rhetoric, is the first part of an oration or discourse, designed to prepare the minds of the hearers for a suitable reception of the succeeding parts; and for this purpose it is necessary that the orator gain the good opinion of his hearers, secure their attention, and give them some general notion of his subject. In order to gain the good opinion of his hearers, the orator, when he introduces the discourse with his own person, will be careful to do it with modesty, and seem rather to extenuate his virtues and abilities than to magnify them; when he sets out with the persons of those to whom the discourse is addressed, it is not unusual to commend them for their virtues, and those especially which have a more immediate relation to the present subject. The other topics which are to be insisted upon for gaining esteem, are principally taken from the subject, as its justice, importance, advantage, or pleasure. In speaking of gaining the attention of his hearers, Cicero says, we shall be heard attentively by one of these three things; if we propose what is great, necessary, or for the interest of those to whom the discourse is addressed. Some account of the subject should always make a part of the *introduction*. As to the composition of this part of a discourse, it should appear easy and natural, and connected with the rest of the discourse: it should be suited to its length; the language of it should be just, easy, and pleasant; it ought neither to be wholly without passion, nor too violent and impetuous. It ought not to be too general. The *introduction*, however, is not an essential part of a discourse, and is sometimes omitted by the best orators. Ward's Or. vol. i. sect. 12.

INTRODUCTOR, in Antiquity, was particularly used for an officer, who introduced the athletes to the stadium, or place where they were to contend.

INTRONATI, the name of an academy at Siena, in Italy.

The members of this academy, contented themselves, at their first institution, with establishing the following six short laws: 1. To pray. 2. To study. 3. To be merry. 4. To offend nobody. 5. Not to credit too lightly. 6. To let the world talk.

INTRUSION, in the Canon Law, signifies the enjoyment of a benefice, or exercise of an office, without a good title to it. See EXTORTION.

The word is derived from *intrudere*, to thrust in, or enter by force.

Intrusion disqualifies the party from ever holding the benefice.

INTRUSIONE, a writ brought against an intruder, by him that hath fee-simple, &c.

INTUITION, among Logicians, the act whereby the mind perceives the agreement or disagreement of two ideas, immediately by themselves, without the intervention of any other: in which case the mind perceives the truth, as the eye doth the light, only by being directed toward it. Thus the mind perceives that white is not black, that three are more than two, and equal to one and two. See IDEA.

This part of knowledge, says Mr. Locke, is irresistible, and like the sunshine forces itself immediately to be perceived, as soon as the mind turns its view that way. It is on this *intuition* that all the certainty and evidence of our other knowledge depends: this certainty every one finds to be so great, that he cannot imagine, and therefore cannot require, a greater. See JUDGMENT, KNOWLEDGE, DEMONSTRATION, &c.

INTUITIVE Evidence, is that which results from INTUITION. Dr. Campbell distinguishes different sorts of intuitive evidence: one resulting purely from intellection, or that faculty which others have called intuition; another kind rising from consciousness; and a third sort from that new-named faculty, *æmulus sensus*, which this ingenious writer as well as several others contend to be a distinct original source of knowledge; whilst others refer its supposed office to the intuitive power of the understanding. Campbell's Rhetoric, vol. i. book i. chap. 5.

IN-TURN, among *Wrestlers*, is when one puts his thigh between those of his adversary, and lifts up his thigh.

INVADIATUS, in our *Old History*, a person accused of any crime, which not being fully proved, he was put *sub debita fide jussione*, and called *invadiatus*.

INVALID, a person wounded, maimed, or disabled for action by age.

At Chelsea and Greenwich are magnificent **HOSPITALS** or rather colleges, built for the reception and accommodation of *invalids*, or soldiers and seamen worn out in the service.

We have also twenty independent companies of *invalids*, dispersed in the several forts and garrisons.

At Paris is a college of the same kind, called *les Invalides*, which is accounted one of the finest buildings in that city.

INVECTED, in *Heraldry*, denotes a thing dated, or surmounted.

Invectid is the just reverse of *engrailed*, in which the points are turned outward to the field: whereas in *invectid* they are turned inward to the ordinary. *Tab. II. Heraldry*, fig. 70.

INVECTIVE, in *Rhetoric*, differs from reproof, as the latter proceeds from a friend, and is intended for the good of the person reprov'd; whereas *invective* is the work of an enemy, and entirely designed to vex and give uneasiness to the person against whom it is directed.

INVENTION denotes the act of finding any thing new; or even the thing thus found.

Thus we say, the *invention* of gunpowder, of printing, &c. The *alcove* is a modern *invention* owing to the Moors.

The Doric, Ionic, and Corinthian orders are of Greek *invention*; the Tullian and Composite of Latin *invention*. Janson ab Almeloveen has written an *Ornamentation of invention*, wherein are shown, in an alphabetical order, the names of the inventors, and the time, place, &c. where they were made. Pincianus has a treatise of old *inventions* that are lost, and new ones that have been made; Polydore Virgil has also published eight books of the *invention* of things. *De Inventis Rerum*.

INVENTION is also used for the discovery of a thing hidden.

The Romish church celebrates a feast on the fourth of May, under the title of, *Invention of the Holy Cross*.

INVENTUS is also used for subtilty of mind, or somewhat peculiar to a man's genius, which leads him to a discovery of things new.

In which sense we say a man of *invention*: Wolfius has made some essays towards an art of *invention*.

INVENTION, in *Painting*, is the choice which the painter makes of the objects that are to enter the composition of his piece.

M. Felicien gives the general name *invention* to every thing that depends on the genius of the painter, as the ordonnance, the disposition of the subject, and even the subject itself, when it is new.

In another place, that author distinguishes *invention* into two kinds; to wit, that which arises immediately from the mind of the painter, and that which he borrows from some other. The first is, when he absolutely invents the subject himself; and the second, when he borrows it from history, fable, &c.

De Piles observes, that *invention* is different from *disposition*; and that these two things together form *composition*: for after having made a good choice of objects proper for the subject, they may be ill-disposed; and then, though the *invention* be ever so good, the disposition or ordonnance will be faulty, and the piece will displeasure.

Of all the parts of painting, *invention*, doubtless, is that which gives the painter the fairest occasions of shewing his genius, his imagination, and his good taste.

INVENTION, in *Poetry*, is applied to whatever the poet adds to the history of the subject he has chosen; as well as to the new turn he gives it.

INVENTION, in *Rhetoric*, signifies the finding out, and choosing of certain arguments which the orator is to use for the proving or illustrating his point, moving their passions, or convincing the minds of his hearers.

Invention, according to Cicero, is the principal part of oratory: he wrote four books *De Inventione*, whereof we have but two remaining.

This *invention* of the orators cannot, according to Isidore, be properly called *invention*; to *invent*, is to discover things not yet known, not to recollect those that are; whereas the use and office of this rhetorical *invention*, is only, out of the stock of knowledge laid up in the mind, to select such articles as make for the purpose.

The same author divides this faculty of *invention* into two parts, the one *typical*, the other *promptuary*: the first points out the way in which we are to pursue the argument; the latter only lays up and disposes things, for which we have frequent occasion, in the mind.

Invention furnishes the orator with those different kinds of arguments and motives which are adapted to the various purposes he has in view. The helps of *invention* are a

lively imagination and readiness of thought, great learning and extensive knowledge, previous confirmation, and clear enlarged apprehensions of the subject. See **ARGUMENTS**, **COMMON PLACES**, and **TOPICS**, &c.

INVENTORY, in *Law*, a catalogue, or schedule orderly made of all a deceased person's goods and effects, at the time of his death, with their value appraised by indifferent persons, which every executor or administrator is obliged to exhibit to the ordinary at such time as he shall appoint.

By 21 Hen. VIII. c. 5. Executors and administrators are to deliver in upon oath to the ordinary, indented *inventories*, one part of which is to remain with the ordinary, and the other part with the executor or administrator; this is required for the benefit of the creditors and legatees, that the executor or administrator may not conceal any part of the personal estate from them. The statute ordains that the *inventory* shall be exhibited within three months after the person's decease; yet it may be done afterwards, for the ordinary may dispense with the time, and even with its being ever exhibited; as in cases where the creditors are paid, and the will is executed.

The use of the *inventory* is borrowed from the civil law: for whereas by the law of the ancient Romans the heir was obliged to answer all the testator's debts; by which means inheritance sometimes became rather prejudicial than profitable; to obviate this inconvenience, Justinian ordained, that if the heir would first exhibit a true *inventory* of all the testator's effects, he should be no farther charged than to the value of the *inventory*.

INVENTORY, in *Trade*, is a list, or particular valuation of goods, &c. See **VALUE**, **APPRAISEMENT**, &c.

INVERSE, is applied to a manner of working the rule of three, or proportion, which seems to go backwards, or contrarily to the order of the common and direct rule.

In the rule of three direct, the first term is to the second as the third is to the fourth; that is, if the second be greater than the third, or less than the first, in any proportion, the fourth is less than the third in the same proportion.—But in the *inverse* rule, the fourth term is as much greater than the third, as the second is less than the first.

In the *inverse* rule, therefore, the proportion is not as the first is to the second so is the third to the fourth; but as the fourth is to the first, so is the second to the third. For instance, in the direct rule we say, If three yards of tapestry cost twenty pounds, how much will fix cost? The answer is, forty. In the *inverse* rule we say, If twenty working men make ten yards in four days, in how many days will forty do it? The answer to this, is in two days. See **RULE of Three**.

INVERSE Method of Fluxions. See **FLUXIONS**.

INVERSE Planning. See **PLANNING**.

INVERSE Properties. See **PROPORTION**.

INVERSION, the act whereby any thing is inverted, or turned backwards.

Problems in geometry and arithmetic are often proved by *inversion*; that is, by a contrary rule, or operation.

INVERSION, in *Grammar*, is where the words of a phrase are ranged in a manner not to natural a, they might be. For an instance: 'Of all vices, the most abominable, and that which least becomes a man, is impurity.'—Here is an *inversion*; the natural order being, this: Impurity is the most abominable of all vices, and that which least becomes a man.

An *inversion* is not always disagreeable, but sometimes has a good effect.

INVERTED Glasses, *Paint*, &c. See the **SUBLIMINES**.

INVESTIGATION properly denotes the searching or finding anything out, by the tracks, or prints of the feet.

Hence, mathematicians, schoolmen, and grammarians, came to use them in their respective researches.

INVESTIGATION of a Theme, is the art, method, or manner of finding the themes of verbs; that is, the primitive tense, mood, and person, of any verb, far removed from its source. To understand a Greek author, it is absolutely necessary to be well acquainted with the method of *investigating* a theme. This theme, in the Greek tongue, is the present tense of the indicative mood.

Cicero was the first who introduced this term into grammar; he gives the title *investigatio thematicus* to that part where he teaches the manner of finding whence any person, or tense, or verb, proceeds, and of reducing it to its primitive word, or finding its indicative.

INVESTING, the act of conferring on any one the right or property, of a fee, dignity, or office, or of ratifying and confirming what has been obtained elsewhere.

The emperor pretends to a right of *investing* several princes, both in Germany and Italy. There was formerly a particular ceremony for the *investing* of bishops. After the election of a knight of the **GARTER**, he is

invested by the sovereign with the two principal ensigns of the order, the Garter and George.—Before his installation he is also invested with the habit of the order.

INVESTING, in the *Military Art*, signifies the opening a siege, and the encamping of an army round the place to block up its avenues, and prevent all ingress and egress.

It is the cavalry that always begins to invest a place.

INVESTING, in *Common Law*, signifies the putting in possession. A tenant is invested by giving him a verge, or rod, into his hands, and administering an oath.

Others define it thus: *investire est in rem sui aliquem in possessionem*, to give livery of seisin, or possession. See **LIVERY**, and **SEIZURE**.

INVESTITURE is used both for the right, and the act, of investing a tenant, or vassal; that is, of receiving the faith and homage by which a vassal becomes seised, and possessed of a fief, by his lord.

Investiture was anciently performed by rehearsing a formula of words; afterwards by the delivery of such things as had the nearest resemblance to what was transferred. Thus, land passed by the delivery of a surt; and to shew the trees were transferred at the same time, a bough was cut and delivered along with it.

In after-times, the things by which *investitures* were made were not so strictly observed.—Many were invested by the delivery of a staff, a glove, a knife, a piece of a cloak, of a strap, and a girdle; or by pricking the thumb, by giving the keys a spit, a blow, a ring, a surt, a bough, a straw, &c. The *investiture* of a kingdom or lordship, was performed by a standard, a banner, a cap, a sword, a bow, arrows, &c.

The symbols were sometimes preferred in the repositories of the houses, and were annexed to the titles.

INVESTITURES were also used with respect to spiritual benefices. These were frequently performed by delivering the crozier and pastoral ring.

The kings of England and France, the emperors of Germany, &c. had formerly this right; so that on the death of a prelate, his clergy sent the crozier, &c. to their sovereign, to be used at the ceremony of *investing* his successor. It is not certain when this custom began; Cardinal Humbert places the commencement of it in the reign of Otho the Great; and it appears, that in the ninth century, the greater part of the European princes made no opposition to the right of electing the bishops, which was both claimed and exercised by the clergy and the people. The first who disputed this privilege with the emperors and sovereign princes, was Gregory VII. he excommunicated the emperor Henry IV. and forbade all ecclesiastics, under pain of excommunication, to receive *investiture* at the hands of secular princes. This occasioned a long and bloody war; the civil and ecclesiastical powers being divided into two great factions, of which one maintained the rights of the emperor, while the other seconded the ambitious views of the pontiff. The laws of Gregory for the abolition of *investitures* were confirmed and renewed by Victor III. and Urban II. the last of whom not only confirmed the laws and anathemas of Gregory, in a council assembled at Piacenza in the year 1055; but published also a prohibitory law in the council of Clermont, forbidding the bishops and the rest of the clergy to take the oath of allegiance to their respective sovereigns. Pascal II. in a council assembled at Rome, A. D. 1102, renewed the decrees of his predecessors against *investitures* and the excommunications, they had thundered out against Henry IV. Pascal, however, was obliged in 1111, to confirm Henry V. in the right of giving *investitures*; but repenting what he had done, he assembled a council in the church at Lateran, in 1112, which solemnly annulled his treaty with the emperor, who was excommunicated in many synods and councils, both in France and Germany. At length, however, Calistus II. engaged him to renounce *investiture* on certain conditions, and peace was concluded between the emperor and pope's legate, at a general diet held at Worms, A. D. 1122. This convention was confirmed the following year in the general council of Lateran, and remains still in force.

INULA, in *Botany*. See **ELÆAGNACEÆ**.

INVOCATION, in *Theology*, an act whereby we adore God, and call on him for his assistance. The Romanists also practise invocation of saints, begging them to intercede with God in their behalf. This is one of the grand articles of dispute between the Romanists and the Reformed.

INVOCATION, in *Poetry*, an address at the beginning of a poem, wherein the poet calls for the assistance of some god, particularly of his Muse, or the deity of poetry. See **MUSE**.

This part is absolutely necessary in an *epic* poem, because the poet relates things which he could not be sup-

posed to know, unless some deity inspired him. Besides this serves his readers as an example of piety and devotion, which ought to be the foundation of his whole work. To their it may be added, that the gods themselves are to have a part in the action; and it is not decent he should let them to work, without first asking them leave.

Indeed, in the course of an *epic* poem there are usually several *invocations*; particularly where any thing extraordinary, or miraculous, comes to be related; as that when Virgil describes the metamorphosis of *Æneïs's* fleet into sea nymphs; but the first *invocation* is always the most considerable.

In the *invocation* both considers two things: the first is, what the poet requests; the second, to what deity he addresses his request. As to the first, Homer has joined the *invocation* to closely to the proposition, that he seems to *invoke* his muse for the whole work.—But Virgil, on the contrary, only requests his Muse to furnish him with a part of his subject; and even mentions what particular part it is he desires.—After proposing his matter in all its extent, he begs the Muse to acquaint him with the cause of it. See **PROPOSITION**.

As to the deity *invoked*, the same author observes, that it must always be, either the divinity that presides over poetry in general, or that which presides over the particular subject of the work. Ovid's *invocation*, in his *Metamorphoses*, is of the latter kind; and so is that of Lucretius: those of Homer and Virgil are of the former kind; they only invoke the Muses; and thus they distinguish between the divinities who preside over poetry, and those who preside over the actions of the poem, and have part in it.

By the way, it may be observed, that the deities *invoked* are not looked on, even by the poets themselves, as divine personages from whom they expect any real assistance. Under the name of Muse they wish for the genius of poetry, and for all the qualities necessary for the execution of their design. These are mere allegories, or numbers of expressing themselves poetically; just as when they personify and make gods of Sleep, of rest, fame, and other natural and moral things. And thus the Muses come to be of all ages, countries, and religions; there are Pagan, Christian, Greek, Latin, and English Muses.

INVOICE, or *INVOCER*, a list, or account, of commodities, with their value, customs, provision, charges, &c. sent by a merchant to his factor, or correspondent, in another country.

INVOICE, *book*, &c. See **BOOK**.

INVOLUCRUM, among *Botanists*, expresses that sort of cup which surrounds a number of flowers together, every one of which has beside this general cup its own particular perianthium. The *involucrum* consists of a multitude of little leaves disposed in a radiated manner. See **COLYX**.

INVOLUNTARY motion. See **MOTION**.

INVOLUTE *cavus*, in the *Hyper Geomety*. See **EVOLUTE**.

INVOLUTION, in *Algebra*, the raising any quantity from its root, to any height, or *POWER*, signified.

Any quantity multiplied by itself, the product is the square of that quantity; the square being again multiplied by the quantity, produces its cube. See **SQUARE** and **CUBE**.

Thus if $a + b$ were to be raised to its second power, it will produce $a^2 + 2ab + b^2$.

And if it be *involved* again, or if that square be multiplied by the root, the cube or third power, will be produced; viz. $a^3 + 3a^2b + 3ab^2 + b^3$, &c. so that the *involution* of any compound quantity is performed by a continual multiplication of it by itself: if the powers of $a + b$ are required, they will be found the same as those of $a + b$, except that the terms in which the exponent of b is an odd number will be negative, because an odd number of multiplications of a negative produce a negative; or, in general, the terms of any power of $a - b$ are positive and negative by turns. See **BINOMIAL Theorem**.

If a quantity consisting of three or more terms is to be *involved*, it may be distinguished into two parts, which are to be raised to any power in the same manner as a binomial; and then by the same rules, the value of these compound parts may be substituted in their stead: thus

$$a + b + c^2 = a^2 + 2ab + b^2 + 2ac + 2bc + c^2.$$

$$\text{And } a + b + c^2 = a^3 + 3a^2b + 3ab^2 + b^3 + 3a^2c + 3ac^2 + 3b^2c + 3bc^2 + c^3.$$

The reverse of *involution* is called **EVOLUTION**. See **EXTRACTION OF ROOTS**, and **ROOT**.

INWARD *sanctifying Angel*, in Fortification: see **ANGLE**.

JOA *mojaba*, in Botany, a name used by some authors for the chamæpitys, or ground-pine.

JOACHIMITES, in Ecclesiastical History, the name of a sect, the followers of one Joachim, abbot of Flora, in Calabria, who was esteemed a prophet while he lived, and left, at his death, several books of prophecies, contained in his Everlasting Gospel, commonly called the Book of Joachim, besides other works: which were condemned, in 1175, by the council of Lateran; and by the council of Arles, in 1260.

One of the spiritual frises, named Gerhard, belonging to the order of FRANCISCANS, undertook to explain the Everlasting Gospel of Joachim, in a book published in 1250, entitled the Introduction to the Everlasting Gospel. In this work St. Francis is declared to be the angel mentioned in the Revelation xix. 6. who had promulgated the true and everlasting gospel of God: it is also asserted, that the gospel of Christ was to be abrogated in 1260, and this new gospel to be published in its room; and that the ministers of this signal reformation were to be humble and bare-footed friars, delicate of all worldly emolument. This absurd book was suppressed by order of pope Alexander IV. in 1255, and at length publicly committed to the flames.

The *Joachimites* were particularly fond of certain ternaries: the Father, said they, operated from the beginning till the coming of the Son; the Son from that time to theirs, viz. the year 1260; and the Holy Spirit then took it up, and was to operate in his turn. Hence they divided every thing that related to men, time, doctrine, and manner of living, into three classes, or states, according to the three persons in the Trinity; every one of which states either had already, or was hereafter to succeed in its turn; and hence they called their divisions *ternaries*.

The explanation given by Joachim, of the Trinity, in opposition to Peter Lombard, which was considered by many as differing little from the Arian system, procured the damnable sentence of his doctrine by Innocent III. in the council of Lateran; but, notwithstanding this papal sentence, Joachim has still a considerable number of adherents and defenders, more especially among those of the Franciscans, who are called *Observants*, or *Friars observants*.

JOH, or the *Book of Job*, a canonical book of the Old Testament, containing the narrative of a series of misfortunes, which happened to a man whose name was *Job*, as a trial of his virtue and patience; together with the conferences he had with his cruel friends on the subject of his misfortunes; and the manner in which he was restored to ease and happiness. This book is filled with those noble, bold, and figurative expressions, which constitute the very soul of poetry.

Many of the Jewish rabbins pretend, that this narrative is altogether a fiction; others think it a simple relation of a matter of fact, just as it happened; while a third sort of critics own the ground-work of the story to be true, but that it is woven in a poetical strain, and decorated with peculiar circumstances, to render the narration more profitable and entertaining.

See an express dissertation on the book of *Job*, in the bishop of Gloucester's Divine Legation of Moses, vol. ii. The bishop is of opinion that this book is a dramatic poem, written by Ezra, some time between the return of the Jews from the captivity of Babylon, and their thorough settlement in their own country, and adapted to the circumstances of their times, by being made allegorical as well as dramatic: that *Job*, who is supposed to have been a real person, that lived a generation or two before Moses, is designed to personate the Jewish people; his three friends, the three great enemies of the Jews, Sanchallu, Tobiah, and Gedem, who, upon their return from the captivity, vexed and obfuscated them in rebuilding their city and temple; *Job's* wife was intended by the poet to represent the idolatrous wives which many of the Jews had taken, contrary to the law, and for which they are reproved by the prophet Nehemiah. Le Clerc also supposes that the book of *Job* was written after the Jews were carried into Babylon, and urges, in proof of this, the frequent Chaldeisms that occur in it.

The learned Grotius apprehends that this book contains a true history, treated in a poetical manner; that the events recorded in it happened in Arabia, whilst the Hebrews wandered in the desert; and that the writer, who was a Hebrew, lived before the time of Ezekiel, but after David and Solomon; and that it was written for the use of the Exiles, transported to Babylon, to confirm them in the worship of the true God, and to teach them patience in adversity. Schultens ascribes the poetical, or dialogue part of this book, the style of which, he says, has all the marks of the most venerable and remote anti-

quity, to *Job* himself; the rest he supposes to be the work of some Hebrew collector. Most of the Jewish doctors believe, that Moses was the writer of this book; and M. Huet supposes that it was written by Moses in his exile in the land of Midian: nor is it improbable that it was designed to prepare the Israelites for their exodus from Egypt, and the hardships of their future peregrination.

JOE *tenis*, *Gala*, in Botany, a genus of the monœcia trigynia class. Its characters are these: it hath male and female flowers on the same plant, and the male flowers are disposed in a loose spike; the chaff of these have valves, including two flowers; the petal hath two oval valves, these have each three hairy flammis, terminated by oblong four-cornered tumours; there are a few female flowers situated at the base of the male spike in the same plant, having a bisulcus chaff, the peral hath two oval valves, and they have a small oval permen, supporting a style divided into two parts, which becomes a hard roundish smooth seed. There are two species, the first of which grows naturally in the islands of the Archipelago, and is frequently cultivated in Spain and Portugal, where the poor inhabitants make a coarse sort of bread of the grain.

JOBBER, a person who undertakes *jobs*, or small pieces of work.

In some Estates, *jobber* is used for a person who buys and sells cattle for others. See **BROKER**.

JOBBENT *naile*. See **NAILE**.

JOCKEY, in the management of horses; the person who trims up, and rides about horses for sale.

JOCKLET, or **YOCKLEAT**, a term used in some parts of Kent, for a little larv which requires but one yoke of oxen to till it.

JOEL, or the *Prophecy of JOEL*, a canonical book of the Old Testament. *Joel* was the son of Pethuel, and the second of the twelve lesser prophets. The style of this prophet is figurative, strong, and expressive. He upbraids the Israelites for their idleness, and foretells the calamities they should suffer as the punishment of that sin; but he endeavours to support them with the comfort that their miseries should have an end upon their reformation and repentance. Some writers, inferring the order of time in which the minor prophets lived from the order in which they are placed in the Hebrew canon, conclude that *Joel* prophesied before Amos, who was contemporary with Uzziah, king of Judah. Archbishop Usher makes this inference from *Joel's* foretelling that drought, chap. i. which Amos mentions as having happened, chap. iv. 7, 8, 9. If we consider the main design of *Joel's* prophecy, we shall be apt to conclude, that it was uttered after the captivity of the ten tribes; for he directs his discourse only to Judah, and speaks distinctly of the sacrifices and oblations that were vainly made in the temple. Lowth.

JOHANNIS, a sect of heathen religious in the East Indies, who never marry, nor hold any thing in private property; but live on alms, and practise strange severities on themselves.

They are subject to a general, who sends them from one country to another to preach; they are, properly, a kind of penitent pilgrims; and are supposed to be a branch of the ancient Gymnosophists.

They frequent, principally, such places as are consecrated by the devotion of the people, and pretend to live several days together without eating or drinking. After having gone through a course of discipline for a certain time, they took upon themselves an impenetrable, and poisonous, to do any thing; upon which they give a taste of their positions, and run into all manner of debauchery.

JOHN—*Christians of St. JOHN*. See **CHRISTIANS** of *St. JOHN Baptist*, *hermits*, &c. See **HERMITS**, *St. JOHN*, *Prester*. See **PRESTER**.

JOHN, or the *Gospel of St. JOHN*; a canonical book of the New Testament, containing a recital of the life, doctrine, and death of our Saviour, Jesus Christ, written by St. JOHN, the apostle and evangelist. See **GOSPEL**.

St. John, according to M. Fabricius, and Le Clerc, wrote his Gospel at Ephesus, after his return from the Isle of Patmos, A. D. 97, at the desire of the Christians of Asia. Wetstein thought that this Gospel might be writ about the year 32, after our Lord's ascension; Baskinge and Lampe suppose that it was writ before the destruction of Jerusalem: Dr. Lardner adopts this opinion, and assigns the date of it to the year of Christ 68. This period brings it nearer to that of the three other gospels, which was about the year 63 or 65, and the Gospel itself, the Jewish design of which was to show how inexcusable the Jews were in not receiving Jesus as the Christ, and to vindicate the providence of God in the calamities already befallen, or now coming upon them, was suitable to the circumstances of the Jews at this period. The

ancients align two reasons for this undertaking: the first is, because in the other three Gospels, there was wanting the history of the beginning of Jesus Christ's preaching, until the imprisonment of John the Baptist, which therefore he applied himself particularly to relate: the second reason was, in order to remove the errors of the Cerinthians, Ebionites, and other sects. But Mr. Lampe and Dr. Lardner have urged several reasons to show that St. John did not write against Cerinthus or any other heretics in his Gospel. Lampe, Prolegom. in Johan. lib. ii. cap. 3. Lardner's Credibility, vol. xv. ch. 9. St. John's bread, see CAROL.

Sweet JOHN, see PINK.

JOHN'S wort, or St. John's wort, *hypericum*, in Botany, a genus of the *polyadelphia polyandria* class. Its characters are these: the flower has a permanent empanclement, divided into five oval concave segments, and has five oblong oval petals, with a great number of hairy stamens, joined at their base in five distinct bodies: it has in the centre a roundish germen supporting one, three, or five styles; the germen afterward becomes a roundish capsule, having the same number of cells as there are styles in the flower, which are filled with oblong seeds. There are many species.

Hypericum is a good vulnerary, detergent, and nervous medicine: it is given with success in spitting of blood, or voiding it by urine; it resolves coagulated blood, promotes the menses and urine, destroys worms, and stands recommended in all nervous cases. A tincture of the flowers in oil olive, made by macerating four ounces of the full blown flowers, fresh gathered, and freed from the cups, in a quart of oil, till the oil is sufficiently coloured, is kept for external purposes in the shops, under the name of *oleum hyperici*, but rarely used.

The seed of the bastard St. John's wort, provokes urine and the menses; and taken in wine is good against the bite of the phalangium (a poisonous spider), and for that species of convulsion called *epileptus*. Oil also impregnated with this plant, is good for the last mentioned disorder, applied externally.

JOHNSONIA, *callicarpa*, in Botany, a genus of the *tetrandria monogynia* class. Its characters are these: the flower has an empanclement of one leaf, cut at the brim into four short segments; it has one tubulous petal, divided into four parts at the brim, and four slender stamens, which are longer than the petal. In the centre is situated a roundish germen, which afterward becomes a smooth globular berry, inclosing four hard oblong seeds. Miller reckons only one species, a native of South Carolina; but Linnaeus enumerates two. The leaves of the American plant were used by Dr. Dale in dropical cases with success.

JOINDER, or JOYNDER, is the coupling, or joining, two persons in one action, or suit, against another.

JOINERY, see JOINER.

JOINING of *issus*, see ISSUE.

JOINT, the juncture, articulation, or assemblage, of two or more things. See ARTICULATION.

JOINTS, in Anatomy. The supplest of the joints may be brought to by long practice from the time of infancy, is surprising. Every common posture-master at a country fair shows us a great deal of this; but the most wonderful instance we have ever had of it, was in the person famous in London several years ago, whose name was Clark, and commonly called Clark the posture-master. This man had found the way, by long practice, to distort many of the bones, which nobody before had ever thought it practicable to alter the position of; and had such an absolute command of the muscles and joints, that he could almost disjoin his whole body; so that he once imposed on the famous Mallens by his distortions, so far that he refused to undertake his cure, as supposing him beyond relief. But, to his amazement, he had no sooner given him over, than the man restored himself to the figure and condition of a proper man, with no distortion about him. See Phil. Trans. N° 242. p. 262.

JOINT-CARTILAGE, or ARTICULATING-CARTILAGE. An articulating cartilage is an elastic substance, uniformly compact, of a white colour and somewhat diaphanous, having a smooth polished surface covered with a membrane, harder and more brittle than a ligament, but softer and more pliable than a bone.

When a joint-cartilage is well prepared by the anatomist, it feels soft, and yields to the touch; but, as soon as the pressure is taken off, it restores itself to its former equality of surface. Its superficies, examined by a glass, appears like a piece of velvet. If we endeavor to peel off the matter of the cartilage in several lamellae, we find it impracticable; but if we use a certain degree of force, it separates from the bone in small pieces, and we never find the edge of the remaining part oblique, but always perpendicular to the subjacent surface of the bone. If

we view this edge through a microscope, it appears like the edge of a piece of velvet; that is, it is seen to be a mass of short and nearly parallel fibres, rising from the bone and terminating at the surface of the cartilage; and the surface of the bone is placed out into a number of small circular dimples, in which the bundles of these fibres are fixed. Thus we may very properly compare the substance of the cartilage to the pile of velvet, and the surface of the bone to the web of silk which is the basis of it.

In both substances the short threads or filaments sink in waves on being pressed, but by the power of elasticity they both recover their perpendicular direction as soon as they are no longer subjected to a compressing force. These perpendicular fibres, doubled, make the greatest part of the substance of the cartilage in its natural state. In the best preparations they seem to make up the whole; but it is probable, that in the recent state there were a number of transverse fibrils serving to connect these erect ones together, and form the whole into a solid body; and that these perish in making the preparation.

We are told by anatomists, that cartilages are covered with a membrane called perichondrium. If they mean the cartilages of the ribs, larynx, ear, &c. there indeed such a membrane is very conspicuous; but the perichondrium of the smooth articulating cartilages is so delicately thin, and so firmly braced upon the surface, that there is great room to doubt, whether it has been rightly understood, or demonstrated.

This membrane has, however, been raised by some late anatomists in pretty large pieces, after macerating, and it is found to be a continuation of that fine smooth membrane which lines the capsular ligament folded over the end of the bone; for when that ligament is inserted on the neck of the bone, or between the insertion of the ligament and the border of the cartilage, it is very conspicuous, and may be pulled up with a pair of pincers; but where it covers the cartilage, it is connected so close, that it is not to be traced while recent, without the greatest care and delicacy. In this particular it resembles that membrane which is common to the eye-lids and the fore part of the ball of the eye, and which is loosely connected with the albuginea, but strongly attached to the cornea. From this description it is plain, that every joint of the human body is invested with a membrane, which forms a complete bag, and gives a covering to every thing within the articulation, in the same manner as the peritonaeum invests not only the parietes, but all the contents of the abdomen.

The blood-vessels of the cartilages are so small, that they do not admit the red globules of the blood, and consequently they remained unknown till they were discovered by the modern method of injections, by which the whole vascular system is filled with a liquid wax, coloured so as to be distinguished from all other things: not even by this method are we able to demonstrate the vessels of the true cartilaginous substance in adult subjects. But the fat, the glands, and the ligaments will be red with injected vessels, while not one coloured speck appears on the cartilage itself. Yet it is evident, that there are vessels there, since in very young subjects after a subtle injection, they become sufficiently obvious. By this means their course is also discovered, and is found to be as follows.

All round the neck of the bone there are a great number of arteries and veins which ramify into smaller branches, and communicate with one another by frequent anastomoses like those of the mesentery. This might be called the *circulus articularis vascularis*, the vascular body of the joint. The small branches of the vessels divide into still smaller ones upon the adjoining surface in their progress to the centre of the cartilage; and we are very seldom able to trace them into its substance, because they terminate abruptly at the edge of the cartilage in the same manner with the vessels of the albuginea of the eye, when they arrive at the cornea. The larger vessels which compose the vascular circle plunge in by a great number of holes, and disperse themselves into branches between the cartilage and the bone. From these again there arises a crop of short twigs, which shoot towards the outward surface. Whether these serve for nourishment only to the part, or whether they do not pour forth a dewy moisture, of service to the functions of the part, is not easily determined. It is to be observed, however, that the distribution of the blood-vessels to the articulating cartilages, is very peculiar, and seems calculated for the obviating of great inconveniences. Had they run to the outer surface, the pressure and motion of the two cartilages must infallibly have occasioned frequent obstructions and inflammations, which would soon have rendered our motions painful, and at last have deprived us of them; but by creeping round the cartilaginous brim where there

is little friction, or under the cartilage where there is none, they are perfectly well defended from these accidents.

It would be very happy, if we could trace the nerves of the cartilages; but in relation to these organs we are obliged to be satisfied by mere conjecture, as to their existence here, as well as in many other parts of the body. And though from the great sensibility of cartilages some persons have supposed, that they were furnished with no nerves at all, yet when we consider that these vessels form necessary to the growth and preservation of any part, we must be forced to acknowledge their existence in this, though we can neither feel them, nor be sensible of their effects.

The articulating cartilages are most happily contrived to all the purposes of motion in the parts. By their uniform surface they move upon one another with ease; by their form, smoothness and firmness, their abrasion is prevented, which else must have happened from such frequent use. By their flexibility, the congruous surfaces are always nicely adapted to one another, and the friction diffused equally over the whole; by their elasticity the violence of any shock which may happen from running, jumping, or other violent motions, is broken and gradually spent; and, as the course of the cartilaginous fibres appears calculated chiefly for this last advantage, we need only, to illustrate it, to reflect upon the difference of ribbing a chamber-stair of wood, and a real one, whose motions are softened in all respects by the cartilages placed in the joint.

The inflexibility of the articulating cartilages is wisely contrived by the great Author of our frame, since it is wholly owing to this that the necessary motions of the body are performed without pain.

An ulcerated cartilage is generally allowed, by the best clinical writers from Hippocrates to the present time, to be a very troublesome disease, and one that is more difficult to cure than a caries of the bones; and that when a cartilage is destroyed, it is never to be recovered again, is also a generally established opinion. Hildanus, in particular, in treating of the diseases of these parts, has observed, that where a cartilage is by any means destroyed, nature usually supplies its place by a callus thrown out from the bone, and that thus a bony ankylosis, or immovable continuity, is produced in the place of a moveable joint. In examining the diseased joints, either after death or amputation, Mr. Hunter observes, that he usually found, according to the nature and stage of the disease, the cartilages in some parts reddish and lax, and in others soft and spongy; or that they were raised up in blisters from the bone, or quite eroded, and perhaps the extremities of the bone carious; and finally, sometimes a bony ankylosis formed, as Hildanus reports; but that he never saw, or indeed heard of, an exfoliation from the surface of the cartilage. Now if we compare the texture of the cartilages, and their morbid appearances together, all these diseased states will admit of a rational solution, as these of perhaps any other part of the vitiated economy. Phil. Trans. N^o 459. p. 521.

It appears from macerating of the cartilages, that their transverse fibrils are extremely tender and dissoluble, and that the cohesion of the parts of the straight fibres is stronger than their cohesion with the bone. When a cartilage, therefore, is inflamed, and soaked in purulent matter, the transverse, or connecting fibres, will soonest give way, and the cartilage will become more or less red and soft. If the disorder goes on a little longer, the cartilage does not throw off a scough, but separates from the bone where the force of the cohesion is least, and where the disease from arrives, by reason of the thinness of the cartilage. When the bone is thus exposed, the matter of the ulcer, or motion of the joint, corrodes or absorbs the bony fibres, and if the continuation is good, these will shoot out a callus, which either cements together the opposite bones of the articulation, or fills up the cavity of the joint, and for the future prevents all motion; but if unfortunately the patient labours under a bad habit of body at the time, the malignancy having put root in the bone, will gain ground every day, and the caries will spread, till at last the only relief will be found the cutting off the limb.

JOINTS, in *Architecture*, denote the separations between the flutes, which are filled with mortar, plaster, or cement.

JOINT, in *Carpentry*, &c. is applied to several manners of assembling, or fitting, pieces of wood together. Thus we say, a *dovetail joint*, &c. See **MORTISE, DOVETAIL**, &c.

JOINT, *universal*, in *Mechanics*, an excellent invention of Dr. Hooke, adapted to all kinds of motions and flexures; of which he has given a large account in his *Cutlerian*

Lectures, printed in 1678. This seems to have given occasion to the **GIMBOLS** used in suspending the sea compass, the mechanism of which is the same with that of Desaguliers's *rolling lamp*.

JOINT-issues, in *Law*, in personal actions several wrongs may be joined in one writ; but actions founded upon a tort, and on a contract, cannot be joined; for they require different pleas and different process.

JOINT-issuery. See **BATTERY**.

JOINT-estate, in *Law*, are two or more persons appointed such by will; in which case they are accounted but as one single person, so that the actions done by one of them are taken to be the acts of all, because they all represent the person of the testator; thus, where two joint-executors are appointed of a lease for years, in right of their testator, one of them may sell the term without the other's joining; and in like manner, where one joint-executor gives a release, the others are bound by it, each having an authority over the whole estate; but a joint-executor is not charged with the acts of his companion any farther than he is actually possessed of the goods of the testator; however, if joint-executors enter into an agreement, that each shall intermeddle with particular parts of the testator's estate, in that case each becomes chargeable for the whole by agreement. It has been held, that two joint-executors cannot sue separate pleas, because their testator, if living, on an action brought against him, could have been allowed but one plea; and that if all the executors are not named in any action brought by joint-executors, the action will abate. As to legacies, the receipt of one executor charges not the other.

JOINT-lives, in *Law*, denote lives that continue during the same time, or that exist together. See **LIFE-annuity**.

JOINT-rule. See *carpenter's joint rule*.

JOINTENANTS, or **JOINT-TENANTS**, in *Law*, those who come to, and hold, lands and tenements by one title, *pro indiviso*, or without partition.

These are distinguished from *seis*, or several tenants, from *partners*, and from *tenants in common*. Anciently they were called *participes*, and not *heredes*. See **SOLICITANT**.

Joint-tenants must jointly plead, and be jointly impleaded and sued by others; which is common to them and **COPARCENERS**. But joint-tenants have a peculiar quality of survivorship, which coparceners have not; so that if there be two or three joint-tenants, and one hath issue, and dies, he, or those joint-tenants that survive, shall have the whole by survivorship.

JOINT-issues, a term used by our lawyers, for what the old writers in medicine have called *hydathorax*, a running of a clear ichor from the joints, when they are either wounded or ulcerated; it is common in the diseases of horses.

JOINETE, in the *Manège*. See **HANDFUL**.

JOINTRESS, or **JOINTERESS**, she that hath an estate settled upon her by the husband, to hold during her life, if she survives him.

JOINTURE, in *Law*, a covenant whereby the husband, or some friend in his behalf, makes over to his wife, on condition of marriage, certain lands and tenements for term of her life, or otherwise, in lieu of dower. Others define *jointure* a bargain and contract of livelihood, adjoined to the contract of marriage; being a competent provision of freehold lands or tenements, &c. for the wife, to take effect after the death of the husband, if the herself is not the cause of the extinction, or forfeiture of it.

And to make a perfect jointure within the Statute of Hen. VIII. c. 10. to bar dower, several things are to be observed. 1. It must be made to take effect on the death of the wife in possession or profit, presently after the decease of her husband. 2. It must be for the term of her own life, or a greater estate; but it may be limited to continue no longer than she remains a widow, &c. 3. It must be made for herself, and to none other, in truth for her. 4. It is to be expressed to be in satisfaction of her whole dower, and not a part of it. 5. It may be made before or after marriage; if it be made before, the wife cannot waive it, and claim her dower at common law; but if it be made after marriage, the wife, at the husband's death, unless the jointure be made by act of parliament. After the death of the husband, the wife may enter into her jointure, and is not driven to a real action, as she is to recover dower by the common law; and upon a lawful eviction of her jointure, she shall be endowed according to the rate of her husband's lands, whereof she was dowerable at common law.

A wife's jointure shall not be forfeited by the treason of the husband; but some covert committing treason, or felony, may forfeit their jointures, and being convicted of

recusancy, they shall forfeit two parts in three of their *jointure* and dower, by 3 Jac. I. c. 4.

JOISTS, or **JOISTS**, in *Architecture*, those pieces of timber framed into the girders and summers on which the boards of floors are laid.

Joists are from six to eight inches square, and ought seldom to lie at a greater distance from each other than ten or twelve inches; nor ought they ever to bear at a greater length than ten feet; or to lie into the wall than eight inches. See *CHIMNEY*.

Sometimes the carpenters furr their *joists*, as they call it; that is, they lay two rows of *joists*, one over the other.

JOIES. See *JESTING*.

ION, in *Natural History*, the name of a gem described by Pliny, and said to be brought from the East Indies; he describes it as being of a purple or violet colour, but rarely very deep in the tinge. It seems to have been a species of amethyst.

IONE pifis, the *Joni-fish*, a name given by many authors to the common shark, the *carcharias* of authors.

It has this name from an opinion that it was the fish which swallowed up the prophet of that name. But there are many objections to such an opinion.

IONAH, or the *Prophecy of JONAH*, a canonical book of the Old Testament, in which is related, that *Jonah* was ordered to go and prophesy the destruction of the Ninevites; but that disobediently attempting a voyage another way, he was discovered by the rising of a sudden tempest, and cast into the sea, where he was swallowed up by a whale. Having lodged three days and three nights in the whale's belly, he was disgorged upon the shore: whereupon, being sensible of his past danger, and surprising deliverance, he betook himself to the journey and embassy to which he was appointed. Arriving at Nineveh, the metropolis of Assyria, he, according to his commission, boldly laid open to the inhabitants their sins and misdeeds, and proclaimed their sudden overthrow; upon which the whole city, by prayer and fasting, and a speedy repentance, happily averted the divine vengeance, and escaped the threatened ruin. *Jonah* was the most ancient of all the prophets whose writings are preserved in the Scripture canon. Some have supposed that he prophesied in the latter end of Jehu's or the beginning of Jehoshaphat's reign, at which time the kingdom of Israel was brought very low by the oppressions of Hazael king of Syria. 2 Kings xiii. 27.

IONICURE, or *JOINTURE*, the fair with *JOINT*.

IONIC, in *Architecture*, the name of one of the five orders of columns. See *Tab. Archit. fig. 26*.

The first idea of the *ionic* was given by the people of Ionia; who, according to Vitruvius, formed it on the model of a young woman, dressed in her hair, and of an easy, elegant figure: whereas, the *Doric* had been formed on the model of a strong robust man.

The *ionic* column is the third in order, and is distinguished from the Composite, in that it has none of the leaves of acanthus in its capital; and from the Tuscan, *Doric*, and Corinthian, by the volutes or ram's-horns, which adorn its capital; and from the Tuscan and *Doric* too, by the channels, or fluting, in its shaft.

This column is a medium between the massive and the delicate orders, the simple and the rich. Its height is eighteen modules, or nine diameters of the column taken at the bottom. When it was first invented, its height was but sixteen modules; but the ancients, to render it still more beautiful than the *Doric*, augmented its height, by adding a base to it, which was unknown in the *Doric*.

M. le Clerc makes its entablature to be four modules, and ten minutes, and its pedestal six entire modules; so that the whole order makes twenty-eight modules ten minutes.

It is said, the temple of Diana, at Ephesus, the most celebrated edifice of all antiquity, was of this order. At present, it is properly used in churches, and religious houses, and in courts of justice, and other places of tranquillity and devotion.

This order has one advantage above any of the rest; and it consists in this, that the fore and hind parts of its capital are different from the sides; but this is attended with an inconvenience, when the ordinance is to turn from the front of the building to the side; to obviate which, the capital may be made angular, as is done in the temple of Fortuna Virilis. Scamozzi, and some other modern architects, have introduced the upper part of the Composite capital, in lieu of the *ionic*, imitating that of the temple of Concord, whose four sides are alike: to render it more beautiful, the volute may be made a little oval and inclining. For the measures of the several parts of the *ionic*, see *COLUMN*.

ionic architecture, *base*, *capital*, *corniche*, *entablature*, *frases*, *pedestal*. See the substantives.

ionic dialect, in *Grammar*, a manner of speaking peculiar to the people of Ionia.

At first, it was the same with the ancient Attic; but passing into Asia, it did not arrive at that delicacy and perfection to which the Athenians attained; instead of that, it rather degenerated in Asia Minor, being corrupted by the admixture of foreign idioms.

In this dialect it was, that Herodotus, Hippocrates, and Galen, wrote.

ionic sect was the first of the ancient sects of philosophers.

The founder of this sect was Thales, who, being a native of Miletus, in Ionia, occasioned his followers to assume the appellation of *ionic*.

It was the distinguishing tenet of this sect, that water was the principle of all natural things.

This is what Pindar alludes to in the beginning of his first Olympic Ode.

ionic transmigration was heretofore a celebrated epocha, which took its rise from the retreat of the Athenian colonies; who, upon the death of Codrus, put themselves under the command of his son Neleus, and established the twelve cities of Ionia in Asia.

These colonies, according to Eratosthenes, were established fifty years after the return of the Heracleids; and, according to Marbani, seventy-seven years after the taking of Troy.

IONKS, or *JOINKS*, in *Ship-building*, vessels very common in the East Indies, about the bigness of our fly-boats, but differing in form of building, according to the various methods of the nations in those parts.

IONQUI, in *Italy*; see *NARCISUS*.

IONTELASPI, in *Italy*; see *CLYPEOLA*.

IO PEAN, among the ancients, an exclamation used on account of a victory, or some prosperous event. Hoffman thinks that *Io Pean* is a contraction of the Hebrew *Yah*, from *Yehovah*, and *PIAN*, *repas*; and was the same with *Yehovah Repas*, i. e. *Domus repas* in *lat.* Something like this exclamation still remains among the Symerones, a people of the West Indies, who on any joyful occasion frequently cry out *Ya Pea*.

JOSHUA, a canonical book of the Old Testament, containing the history of the wars and transactions of the person whose name it bears. This book may be divided into three parts; the first of which is a history of the conquest of the land of Canaan; the second, which begins at the twelfth chapter, is a description of that country, and the division of it among the tribes; and the third, comprised in the two last chapters, contains the renewal of the covenant he caused the Israelites to make, and the death of their victorious leader and governor. The whole comprehends a term of seventeen, or, according to others, of twenty-seven years.

JOVIALE arcanum. See *ARCANUM*.

JOVIALE herardium. See *HERARDIUM*.

JOURNAL, a day-book, register, or account of what passes daily. See *DIARY*.

JOURNAL, in *Merchants Accounts*, is a book into which every particular article is posted out of the waste book, and made debitor. This is to be very clearly worded, and fairly engrossed. See *Journal Book*.

JOURNAL, in *Sea Affairs*, is a register kept by the pilot, and others, wherein notice is taken of every thing that happens to the ship from day to day, and from hour to hour, with regard to the winds, the tides, the rakes, soundings, &c. in order to enable him to adjust the reckoning, and determine the place where the ship is.

In all sea journals, the day, or what is called the twenty-four hours, begins at noon, and is counted thence twenty-four hours to the next noon: the first twelve hours, from noon to midnight, are marked with P. M. signifying after mid-day; and the second twelve hours from midnight to noon are marked with A. M. signifying after midnight: so that the ship account is twelve hours earlier than the shore account of time. There are various ways of keeping journals, according to the different notions of mariners concerning the articles that are to be entered. Some writers direct the keeping such a kind of journal as is only an abstract of each day's transactions, specifying the weather, what ships or lands were seen, accidents on board, the latitude, longitude, meridional distance, course, and run. Their particulars are to be drawn from the ship's *look-book*, or from that kept by the person himself. Other authors recommend the keeping only of one account, including the log-book, and all the work of each day, with the deductions drawn from it. The form of this latter kind of journal, with an example of the work of a single day, is as follows:

Journal

J O U R N A L

Abstract of a Journal from England towards Madeira.

Remarks on board.

21. 13th October.
 These twenty-four hours hard gales, and cloudy weather, accompanied with hard rains.
 Handed fore-top sails.
 At 10 P. M. heard a gun at a distance.
 At 2 A. M. saw to the N. N. E. the flash of a gun, and after fifty-six beats of the pulse at the wrist we heard the sound, by which we judged the distance to be about eleven miles and a ship in distress. Bore away to speak with her.
 At six, having greatly over-run the distance, and finding nothing, concluded she was gone down, so hauled our wind, and stood to the S. W.
 No observation this day.
 Variation 12 point west.
 Departure, latitude = 41° 16' N.
 Difference of Latitude = 0 24' S.
 Present latitude = 40 52' N.
 Sum of latitudes = 82 08'
 Middle latitude = 41 04'
 Departure, longitude = 13 33' W.
 Difference of longitude = 2 06' W.
 Present longitude = 15 39' W.

M. P.

Lizard's latitude = 49° 57' N. 3470
 Ship's latitude = 40 52' N. 2691

Diff. latitude = 9 05' 779
 Or = 554 miles.
 Lizard's longitude = 5° 14' W.
 Ship's longitude = 15 39' W.

Diff. longitude = 9 25' = 565m.
 Lizard bears N. 37° 45' E.
 Distance 685 miles

M. P.

Madaira's latitude = 32° 38' N. 2073
 Ship's latitude = 40 52' N. 2691

Diff. latitude = 8 14' 618
 Or = 494 miles.
 Madaira's long. = 16° 51' W.
 Ship's longitude = 15 39' W.

Diff. longitude = 1 12 = 72 m.
 Madaira bears S. 6° 30' W.
 Distant 505 miles.

JOURNAL is now become a common name for news-papers, which detail the daily transactions of Europe.

JOURNAL is also used for the title of several books which come out at stated times; and give abstracts, accounts, &c. of the new books that are published, and the new improvements daily made in arts and sciences.

The first journal of this kind was, the *Journal des Savans*, printed at Paris: the design was set on foot for the sake of such as are too busy or too lazy, to read the entire books themselves. It seems an excellent way of satisfying a man's curiosity, and becoming learned upon easy terms; and so useful has it been found, that it has been executed in most other countries, though under a great variety of titles.

Of this kind are the *Acta Eruditorum* of Leipzig; the *Nouvelles de la Republique des Lettres* of Mr. Bayle, &c. the *Bibliothèque Universelle, Chronique, et Ancienne et Moderne*, of M. le Clerc; the *Memoirs de Trevoux*, &c. In 1693, Juncker printed, in Latin, an Historical Treatise of the Journals of the Learned, published in the several parts of Europe; and Wolfius, Struvius, Morhoff, Fabricius, &c. have done something of the same kind.

The Philosophical Transactions of London, the *Memoirs of the Royal Academy of Sciences*; those of the *Academy des Belles Lettres*; the *Miscellanea Naturæ Curiosum*; the experiments of the *Academy del Cimento*; the *Acta Philo-cosocorum Naturæ et Artis*, which appeared from March 1686, to April 1687, and which are a history of the Academy of Bresle; the *Miscellanea Resolventia*, or Memoirs of the Academy of Berlin; the *Commentaries of the Academy of Petersburg*; the *Memoirs of the Institute at Bologna*, the *Acta Literaria Suecica*, the *Memoirs of the Royal Academy of Stockholm*, begun in 1740, the *Commentarii Societatis Regiæ Gottingensis*, begun in 1750, &c. &c. are not so properly Journals, though they are frequently ranked in the number.

Juncker and Wolfius give the honour of the first invention of Journals to Photius. His Bibliotheca, however, is not altogether of the same nature with the modern Journals; nor was his design the same. It consists of abridgements, and extracts of books which he had read during his embassy in Persia. M. Salo first began the *Journal des Savans* at Paris, in 1665, under the name of the *Siècle de Holoville*, but his death soon after interrupted the work. The Abbé Gallois then took it up, and he, in the year 1674, gave way to the abbé de la Roque, who continued it nine years, and was succeeded by M. Cusa, who carried it on till the year 1702, when the abbé Bignon instituted a new society, and committed the care of continuing the Journal to them, who improved and published it under a new form. This

society is still continued, and M. de Voyer has had the inspection of the Journal, which is no longer the work of any single author, but of a great number.

The other French Journals are the *Memoirs and Conferences of Arts and Sciences*, by M. Dennis, during the years 1672, 1673, and 1674; *New Discoveries* in all the parts of Physics, by M. de Bagny; the *Journal of Physics*, begun in 1684, and some others, discontinued almost as soon as begun.

Romier's *Journal de Physique*, begun in July 1771, and continued to the present time 1780, is 10 vols. quarto.

The *Nouvelles de la Republique des Lettres*, News from the Republic of Letters, were begun by M. Bayle in 1684, and carried on by him all the year 1687, when M. Bayle being disabled by sickness, his friends, M. Bernard and M. de la Roque, took them up, and continued them till 1690. After an interruption of nine years, M. Bernard resumed the work, and continued it till the year 1710. The History of the works of the Learned, by M. Bagnage, was begun in the year 1686, and ended in 1710. The Universal Historical Library, by M. le Clerc, was continued to the year 1693, and contained twenty-five volumes. The *Bibliothèque Choisie* of the same author, began in 1703. The *Mercury of France* is one of the most ancient Journals of that country, and is continued by different hands: the *Memoirs of the History of Sciences and Arts*, usually called the *Journal des Trevoux*, from the place where they were first begun in 1701. The *Essays of Literature* continued to a twelfth volume in 1702, 1703, and 1704, which only take notice of ancient authors. The *Journal Littéraire*, by Father Hago, began and ended in 1705. At Hamburg, they have made two attempts for a French Journal, but the design failed: an *Ephemerides Savantes* has also been undertaken, but that soon disappeared. A *Journal des Savans*, by M. Dartin, appeared in 1694, and was dropped the year following. That of M. Chauvin, begun at Berlin in 1696, held out three years; and an essay of the same kind was made at Geneva. To these may be added, the *Journal Littéraire*, begun at the Hague in 1715; and that of Verdun, and the *Memoirs Littéraires de la Grande Bretagne*, by M. de la Roche; the *Bibliothèque Angloise*, and *Journal Britannique*, which are continued in English books alone. The Italian Journals are, that of abbot Nazari, which lasted from 1668, to 1681, and was printed at Rome. That of Venice began in 1671, and ended at the same time with the other: the authors were Peter Moretti, and Francis Milleti. The *Journal of Parma*, by Roberti and Father Bacchini, was dropped in 1690, and refused again in 1692. The *Journal of Ferrara*, by the abbé

de la Torre, began and ended in 1691. La Galería di Minerva, in 1696, is the work of a society of men of letters. Seigneur Apollonio Zeno, secretary to that society, began another *Journal* in 1710, under the protection of the grand-duke: it was printed at Venice, and several persons of distinction had a hand in it. The *Fatti Eruditi della Biblioteca Volante*, were published at Parma. There has appeared since, in Italy, the *Giornale dei Letterati*.

The principal among the Latin *Journals* is that of Leipzig, kept under the title of *Acta Eruditorum*, begun in 1682: P. P. Manzani began another at Parma. The *Nova Litteraria Maria Balthici*, lasted from 1693, to 1708. The *Nova Litteraria Germanica*, collected at Hamburg, began in 1703. The *Acta Litteraria ex Manuscriptis*, and the *Bibliotheca curiosa*, begun in 1705, and ended in 1707, are the work of Struvius. Meff. Kuster and Sike, in 1697, began a *Bibliotheca novorum Librorum*, and continued it for two years. Since that time there have been many Latin *Journals*; such, besides others, is the *Commentarii de Libris in Scientia Naturali et Medica editis*, by M. Ludwig. The *Swiss Journal*, called *Nova Litteraria Helvetica*, was begun in 1752, by M. Schenker; and the *Acta Medica Hafnensia*, published by T. Bartholin, make five volumes from the year 1671 to 1679.

There are two Low-Dutch *Journals*; the one under the title of *Boeckzal van Europe*; it was begun at Rotterdam in 1692, by Peter Rabbus; and continued from 1702 to 1708, by Sewel and Garen; the other is done by a physician, called Reiter, who began in 1710. The German *Journals* of best note are, the *Monatlichen Unterredungen*, which held from 1686 to 1693. The *Bibliotheca curiosa*, begun in 1704, and ended in 1707, both by M. Tenzel. The *Magazin* of Hamburg, begun in 1728, by M. Schenker; and the *Acta Medica Hafnensia*, published by T. Bartholin, make five volumes from the year 1671 to 1679.

The English *Journals* are, the *History of the Works of the Learned*, begun at London 1690. *Censura Temporum*, in 1708. About the same time there appeared two new ones, the one under the title of, *Memoirs of Literature*, containing little more than an English translation of some articles in the foreign *Journals*, by M. de la Roche; the other a collection of loose tracts, entitled, *Bibliotheca curiosa*, or a Miscellany. These, however, with some others, are now no more; but are succeeded by the *Monthly Review*, which began in the year 1750, and gives a character of all English literary publications, with the most considerable of the foreign ones: the *Critical Review*, which began in 1756, and is nearly on the same plan; besides these, we have several monthly pamphlets, called *Magazines*, which, together with a chronological series of occurrences, contain letters from correspondents, communicating extraordinary discoveries in nature and art, with controversial pieces on all subjects. Of these, the principal are those called, the *Gentleman's Magazine*, and the *London Magazine*, which both began about the year 1730.

JOURNCHOPPERS, in our *Old Writers*, regrators of yarn; which formerly, perhaps, was called *jaurs*. They are mentioned in the *Ist*. 8 Hen. VI. c. 5.

JOURNEY, *Sabbath Day's*. See **SABBATH**.

JOURNEY-MAN, formed from the French *journee*, a day's work; anciently signified a person who wrought with another by the day, though now, by the statute, it extends to those likewise who covenant to work with another in their occupation or trade by the year.

JOULOPPED, in *Shedley*, a term applied to the gills of a cock, when borne of a different tincture from his head.

JOY, in *Etica*, is that passion which is produced by love, regarding its object as present, either immediately, or in prospect; is really, or imagination. This passion has been found to increase the **RESPIRATION** and urine of human bodies. See **PLEASURE**, and **PAIN**.

JOYNERS *Profess*. See **PERKS**.

JOYNERY, the art of working in wood, and of fitting or joining various parts or members of it together.

The French call it *menuiserie*, from *menuisier*, small work; by which it is distinguished from *carpennerie*, which is conversant in the larger and less curious work.

JOYNERY, *Colours of*. See **COLOURS**.

JOZO, in *Ichthyology*, the name of a small sea-fish, of the sea-gudgeon, or rock-fish kind, common in the Medi-

terranean, and called *gobius albus* by some authors. It is brought to market at Rome and Venice.

IPACACUANHA, or **IPACACUANHA**, in *Pharmacy*, a little wrinkled root, about the thickness of a moderate quill, brought hither from several parts of the West-Indies; much used as an emetic, and against diarrhoeas and dysenteries.

The first European who brought this root into use, was an apothecary of Brazil, whose name was Michael Tristram. The book which this author published on this subject falling into the hands of the English, is translated into our language, and stands, among a number of like accounts, among Purchas's Pilgrims.

He says it is an excellent remedy against dysenteries and fluxes of all kinds. He says also, in his description, that the stalks are a quarter of a yard long, and the roots nearly as much; and that the leaves grow only four or five upon a plant.

This agrees very well with all that we have since discovered of this plant; and the method of using it at that time, we find, was not as a vomit; but they boiled the fresh root, and steeped it about twelve hours in water, at the end of which time the patient drank the water early in the morning; it operated by stool; but after its operation, the natural purging and voiding of blood ceased. This seems the original account we have of this drug. De Lasi from this compiled his account; which is almost a literal translation of this into Latin; from his hint Fido and Margrave enquired after it more carefully upon the spot, and from them came the first accurate accounts we had of it; so that all seems, as arising, deduced from Michael Tristram's account of it. Miller apprehends that the plant which furnishes the true *ipacacuanha* belongs to the genus of *trifolium*, or *salix ipacacuanha*.

There are four kinds of *ipacacuanha*; viz. a brown, a black, a grey, and a white one: though only two, viz. the grey or ash-coloured and brown are met with in the shops. The grey is most esteemed in physic; though the brown is that the most used, as being easiest had;—the latter is firm, twisted, difficult to break, of a sharp bitter taste, and grows plentifully not far from Carthagena.—The root of the grey *ipacacuanha* is longer than any of the other sorts; it is also more violent in its operation: it comes from Peru, by the way of Porto-Bello. The Spaniards call it *terrevello*. The white *ipacacuanha* differs from the others, not only in colour but in figure too, being less twisted or rugged than they; and more resembling the root of white dittany. This grows in Brazil and Martimeo.

There are divers false species of *ipacacuanha*, or roots, which, on account of their external appearance, bear the denomination of *ipacacuanha*, and are sometimes sold for it. Dr. Douglas mentions two, the one white, resembling the true white, only larger in size, flatter, and softer to the touch; the other brown, of a deeper colour than the true brown, and sometimes mixed with red, whence it has also been called red *ipacacuanha*. These are both produced in Maryland and Virginia, where they are used as vomitives by the lower sort. Sir Hans Sloane has discovered, that the latter is no other than the root of a poisonous apocynum, described by him in his Natural History of Jamaica. See *Phil. Trans.* N° 410.

The genuine *ipacacuanha* has scarcely any smell, unless during its pulverization or infusion in liquors, when it emits a faint nauseous one. Geoffroy observes, that in pulverizing considerable quantities, the finer powder that flies off, is apt to affect the operator with difficulty of breathing, a spitting of blood, a bleeding at the nose, or a swelling and inflammation of the eyes and face, and sometimes of the throat; which symptoms go off in a few days, spontaneously, or by the aid of venesection.

This root is the mildest and safest emetic that has yet been discovered. The common dose is from ten grains to a scruple, and upwards; though many instances occur of constitutions, on which two or three grains operated sufficiently. Where it falls as an emetic, it commonly purges; and fifteen grains of jalap, with two or three of *ipacacuanha*, have been found to purge more than twice the quantity of jalap by itself. This medicine has great efficacy in dysenteries, not only when used as an emetic, but when taken in such small doses as scarce to affect the greater emenities. In common cases it soon performs a cure, by bringing on a free diaphoresis or plentiful sweat, after the patient has taken a pulse or two, and is covered up warm in bed. In purist or malignant dysenteries, it requires to be continued for several days, and repeated as an evacuant, with the assistance of rhubarb, cordial antiseptics, and mild opiates or astringents. In cases requiring plentiful evacuation, or

when the offending matter is lodged deep, *see* John Pringle recommends it to be given in small doses, and repeated at proper intervals, till vomiting or purging comes on. *Prel.*

The bark of *ipeacuanha* is said to be preferable to its root, as an emetic acting equally well, and with equal safety, in a smaller dose, either in powder, or infusion. Six grains of the bark, infused for a night in an ounce and a half of old Rhenish, proves a good emetic. See Phil. Trans. N° 476. sect. 10.

The brown *ipeacuanha* yields, by distillation, a smaller quantity of oil than the grey; and the last portion of the spirit which comes over with the oil, on urging the fire to the greatest violence, though it be considerably acid to the taste, yet does not seem to contain less, but rather more volatile particles than the spirit drawn in the same manner from the grey. On mixing the spirits of both kinds also with salt of tartar, the volatile parts of that from the brown, escape with more rapidity than those from the spirit of the grey, and affect the nose more fully.

It is unusual to conclude from hence, that if the brown *ipeacuanha* contains less oil than the grey, it also contains less resin; and that as this last portion of spirit contained more volatile parts, it must usually be expected that it should prove more violent in its operation than the grey. This observation also, which is counterbalanced by fact, may in some degree favour the opinion of its *see* who affirm, that the purgative virtues of medicines are excited by a volatile salt, and that they are more or less violent, as they contain more or less of this salt.

The brown *ipeacuanha*, as well as the grey, will afford two sorts of extracts, a resinous and a saline one; but both these are yielded in a smaller quantity from the brown than from the grey, and consequently the residuum is always greater from the brown. Eight ounces of the grey *ipeacuanha* yield, with spirit of wine, ten drams of the resinous extract; the same quantity of the brown treated in the same manner, yields only six drams. From the residuum of this quantity of the grey kind, thus distilled only of its resin by the spirit, there may be procured, by a watery solvent, two ounces of a saline extract; but the residue of the same quantity of the brown will yield only five or six drams of this extract; by the same treatment. The residue of the grey, thus distilled of its resinous and saline parts, will weigh four ounces; and the residue of the brown, after the same treatment, will weigh near six ounces. Hence it is very evident, that the active principles are much more abundant in the grey than in the brown kind of this useful root.

Neumann says, that sixteen ounces of good *ipeacuanha*, will yield three ounces of resinous matter, in which its virtue consists, by means of spirit of wine; and from the same quantity, by means of water, five ounces of gummy matter were extracted.

If the process of this analysis be varied, and the watery menstruum used first, the proportion of the saline extract will be greatly increased by it, and that of the resinous greatly diminished; eight ounces of the grey *ipeacuanha*, thus treated, yielding three ounces and a half of saline extract, and only thirty-six grains of the resinous one afterwards by spirit of wine; and the same quantity of the brown yielding one ounce and three drams of the saline extract, and only twenty-four grains of the resinous one, by means of spirit of wine afterwards used. From all this it is easy to perceive, that the brown *ipeacuanha* contains much less of the active parts, and much more of the terrestrial than the grey; and yet it is equally certain from trial, that the brown is much more violent in its operation than the grey.

This seems a perplexing sort of paradox; but to explain it we must remember, that the virtues of medicines are not to be measured by their bulk nor their weight, the most powerful of all acting in the smallest quantities. It has been observed, that the last portion of spirit drawn from the brown is more pungent and strong than that from the grey; and probably this part of the root has as much power to irritate the internal parts of the intestines as the resinous parts.

Small doses of *ipeacuanha* are recommended in diarrhoeas of a more simple kind, as well as in dysenteries; and in the flux albus, we hardly know a better medicine. See UTERINE Haemorrhage.

The best menstruum for extracting the entire virtue of the root, appears to be a mixture of one part of pure spirit, with two or three parts of water. In the former, wine is employed; an ounce of the root is macerated or digested in a pint of Canary or mountain, to which some add a quarter of an ounce of dried orange peel. These infusions, in doses of from half an ounce, or less, to an ounce and upwards, prove mildly emetic. Lewis Mat. Med.

IPCACUANHA, *hesler*, in *Batany*, is a species of *ASCLEPIAS*, or SWALLOW-WORT.

IPCACUANHA, *falsæ*, or Dr. Tinker's wood, *tristatum*, in *Batany*, a genus of the *pentstemonia monogyna* class. Its characters are these: the flower has a permanent empalement of one leaf, cut into five segments; it has a tubulose flower of one petal, with a short brim, cut into five parts, which stand erect; and five slender filaments, the length of the tube, terminated by oblong anthers; with a roundish germen, supporting a cylindrical style, crowned by a thick stigma; the germen afterward becomes an oval berry with three cells, each including one hard, three-cornered, oblate seed. There are two species.

Both these plants are natives of Virginia, and some other northern parts of America, where their roots have been frequently used as an emetic, and are commonly called *ipeacuanha*. One of the first persons who brought the roots into use was Dr. Tinker, from whence many of the inhabitants have called them by the name of Dr. Tinker's wood. The leaves of the first sort greatly resemble those of the true *ipeacuanha*, but the roots are of a different form. Miller.

IPCACA GUACA, in *Ornithology*, the name of a Brazilian species of duck. It is of a middle size between the duck and goose and is kept tame there for breeding and eating. It will fatten as well on dry land as when it has the use of water, and lays a vast number of eggs.

IPCACATI *opca*, in *Ornithology*, the name of a Brazilian species of duck called *pata* by the Portuguese; the word in that language expressing goose. It is nearly of the size of the goose, but is exactly of the shape and figure of the common duck. It is very common in the Brazilian rivers, and is fleshy and well tasted.

IPCUCU, in *Ornithology*, the name of a Brazilian bird of the wood-pecker kind, called by Mr. Ray, *picus varius Brasiliensis*. It is of the size of a common pigeon. Its beak is straight, and very hard and sharp, and it pierces the bark and wood of trees with it, in the same manner as the European kinds.

IPERAQUIBA, in *Ichthyology*, a name by which some have called the *ramora*, or sucking-fish, called also by the Portuguese, *peixe pegador*, and *peixe pilolo*.

IPOMOEAE, *see* QUAMOCILIT.

IPPO, in *Natural History*. See MACASSAR Pish.

IPPOSELINUM, or *HIPPOSELINUM*, in *Batany*, a name given by the ancients to the plant from the roots of which the insect myrrh was obtained by incision. Some also have called this plant *pyrrhus*; but it is evident, that it could not be the same with the *hipposelinum* or *pyrrhus* of our authors, which is the herb Alexander, since the juices of this plant have no resemblance to myrrh. Dioscorides calls the plant *pyrrus*, and distinguishes it from the *pyrrhus* of those times; but others have made the *pyrrus* and *pyrrhus* the same.

IRACUNDUS, in *Medicine*, a name given by some authors to one of the muscles of the eye, called also the *rectus exterior* and *obliquus*. It is one of the *oculorum recti* such of Albinus, and is called by him and Douglas, as well as many others, the ABDUCTOR.

IRASCIBLE, in the *Old Philosophy*, a term applied to an appetite, or a part of the soul, where anger, and the other passions, which animate us against things difficult, or odious, were supposed to reside.

Of the eleven kinds of passions attributed to the soul, philosophers ascribe five to the *irascible* appetite; viz. wrath, boldness, fear, hope, and despair; the other six are charged on the concupiscible appetite; viz. pleasure, pain, desire, aversion, love, and hatred.

Plato divided the soul into three parts; the reasonable, *irascible*, and concupiscible parts. The two first, according to that philosopher, are the corporeal parts of the soul, which give rise to our passions; the last, Plato fixes the seat of the *irascible* appetite in the liver, and of the concupiscible in the liver; as the seat of the blood and spirits, which alone affect the passions.

IRENARCHA, *spargano*, composed of *spargano* and *archa*, from *arche*, command, a military officer in the Greek empire, whose business was to provide for the peace, security, and tranquillity, of the provinces. In Justinian's code it is mentioned, that *irenarcha* are sent into the provinces to maintain the public peace, by punishing crimes, and putting the laws in execution. Besides this, there was another *irenarcha* in the cities, to whom belonged the preserving of peace, and quelling sedition among the citizens. This officer was sometimes called *profectus urbis*.

The emperor Theodosius and Honorius suspected the office of *irenarcha*, on account of their abusing their trust, and distilling and persecuting the people, instead of maintaining peace among them.

IRINGIUM, a name given by some of the old writers on the materia medica, to a root called *ferula* by the Arabians, and which, from the similitude of the Latin name with the word *eryngium*, many have supposed to be the same root which was well known to the Greeks, and

and Romans in medicine; and still is in great repute with us on the same occasion.

It is possible that the *iridium* may be the same with the *ginger* or *gingembre*, so famous in the East at this time for the same virtues.

IRIS, rainbow, in Physiology. The word is Greek, *iris*, supposed by some to be derived from *iris*, I speak, I tell, as being a meteor that is supposed to foretell, or rather to declare, RAIN. See RAINBOW.

IRIS, in Anatomy, a striped variegated circle round the pupil of the eye, formed of a duplication of the uvea.

The *iris*, in different subjects, is of several very different colours, whence the eye is denominated *grey*, *black*, &c. in its middle is a perforation, through which appears a little black speck, called the *pupil*, or *apple of the eye*, round which the *iris* forms a ring.

When the aqueous humour of the eye is evacuated at a wound or ulcer of the cornea, there is danger of the *iris* growing to it. To prevent this, the patient is to be exposed to the light from time to time, till the cornea is again raised by the aqueous humour. The light occasions a motion in the *iris*, which may prevent its adhesion.

IRIS is also applied to those changeable colours, which sometimes appear in the glasses of telescopes, microscopes, &c. so called from their similitude to a rainbow. The same appellation is also given to that coloured spectrum, which a triangular prismatic glass will project on a wall, when placed at a due angle in the sun-beams.

IRIS, the flower de luce, in Botany, a genus of the *triandria monogyna* class. Its characters are these: the flowers are inclosed in spathe (or sheath), which are permanent; the flowers are divided into six parts, the three outer oblong, obtuse, and reflexed; the three inner erect, and ending in acute points; they have three awl-shaped stamens, which lie upon the reflexed petals; under the flower is situated an oblong germin, which becomes an oblong angular capsule with three cells, filled with large seeds. There are nineteen species.

The Florentine dry *iris*, or orris-root, is an expectorant and attenuant. It is given with success in asthma, and many other disorders of the breast and lungs. The dose is from ten to fifteen grains in powder. It is used also in perfumes; in stercoratory powders, and for communicating a grateful flavour, resembling that of raspberries, to wines and spirits. The juice of the fresh root of our *iris*, is an excellent medicine in dropsies; and the best way of giving it is with white wine, in doses from one or two drams to three or four ounces, which must be taken every two or three days: it is a strong irritating cathartic, works both by vomit and stool, and discharges a very great quantity of phlegm. The bluish expressed juice of the flowers changes, with the addition of a little lime-water, into a fine green; and it is thus directed in foreign pharmacopoeias for tinging some of the unctuous compositions called odoriferous or apopleptic balsams.

We have a great many species of this plant preserved in gardens, and most of them are very beautiful; their roots are tuberous and increase very fast, and all the species are easily propagated by parting them. The best season for doing which, is in August, when their flower-leaves are decayed, and the whole plant begins to change colour; but this should always be done when the weather is moist, so that if the month of August should prove very dry, it should be deferred till September, though it is best to do it sooner if it can be. They all love a shady moist place. If too much dung is used to the ground, it rots their roots; and if they stand exposed to the sun, their flowers are but of very short duration. They should be taken up once in two years, to prevent their extending their roots too far, for they are apt to spread, and to harbour all sorts of vermin.

The various may raise the several species from their seeds; which if taken from the choicest flowers, and cultivated with care, usually afford a fine variety in the flowers of the plants they produce. They should be sown soon after they are ripe, on an east border: they will come up in spring, and the year following will flower. Miller.

Babius iris, siphis, in Botany, this is a species of *iris* in the Linnaean system. Its characters are these: the flowers have each a permanent spathe or sheath, and have six petals, the three outer broad, obtuse, and reflexed, and the inner erect, pointed, and joined to the other at their base; they have three awl-shaped stamens, which lie upon the reflexed petals, and are terminated by oblong depressed summits; and an oblong germin under the flower, supporting a short style, crowned by a tripartite stigma. The germin becomes an oblong angular capsule with three cells filled with roundish seeds.

We have several species of this beautiful plant cultivated in our gardens, where they are called *babius iris*; and besides these, a vast number of varieties or new flowers,

as the florists call them. The culture of these being the same with that of several other plants of the same sort, which are much valued for their flowers, it may not be amiss to give it at large.

There should be great care to save the seeds of the finest and strongest flowers, and in September some shallow pans or boxes must be placed with holes at their bottoms to let out the moisture, and then filled with light and fine earth. On this the seeds must be sown pretty thick; and as evenly as may be; half an inch of the same earth must be sifted on these, and the boxes must then be set where they may have the morning sun; and if the weather proves very dry, they must be gently watered at times. They must remain in this situation till October, and then must be removed to a place where they may have the benefit of the sun as great a part of the day as may be; here they must stand the winter, keeping the boxes very carefully clear from weeds.

In the spring the young plants will appear, and they should then be removed to their first situation, where they may have only the morning sun; and if the weather be dry, they must be watered at times. In June their leaves will decay, and they must then have half an inch of fresh earth sifted over them, and be left in their situation till October, when they must be removed to the same place as before for the winter.

In the spring the leaves will appear again; and when they are again perished, the earth must be taken out of the boxes, and sifted to separate the roots, which must then be planted at three inches distance on a bed of the same light earth; they must be buried three inches deep, and in the spring following must have about half an inch of fresh earth sifted over them; the leaves will this year appear and decay as before; and the following year, in June, they will most of them flower, when the finest flowers should be marked, that their roots may be taken particular care of. The following year the remainder, which did not flower at first, will produce their flowers; such of these as are finer than the rest, should be marked in the same manner, and the roots of these choice kinds be preserved with particular care. Whatever fine or new flower is thus raised from seed, may be afterwards propagated by off-sets from roots, which being planted out, will flower the second year, and often produce even finer flowers than the mother-roots.

The roots of these flowers should be taken out of the earth only every other year; this should be done just when the leaves are decayed, and they should not be kept out of the earth above a fortnight.

The earth in which these flowers thrive best, is a light sandy loam; and if it be taken up with the turf and the grass rotted among it before it is used, it will be so much the better. They do not delight in a rich danged soil, nor should they be placed where they are too much exposed to the sun; for besides that the flowers soon fade in these places, the roots are also always found to decay; but in an east border, where they may have the sun till eleven o'clock, and where the ground is not too moist, nor over dry, they will stand a long time in flower, and thrive extremely well.

IRIS, lutea palustris, the yellow flag-flower, is a species of *iris* which grows naturally in ditches and moist places, in most parts of this country. The common people of Scotland have found out an use of this plant, which has escaped the most accurate writers on botany. In that country the common ink is made of it. They cut some of these roots into thin slices, and either boil or infuse them in water till the liquor is highly tinged with them; they then pour it clear off, and then putting into it the blade of a knife, or any other piece of iron, they rub it hard with a rough white pebble, common there, and by degrees the liquor becomes black; they continue rubbing it till it is as deep a black as they require, and it is a tolerable good ink. Phil. Trans. N° 317.

The juice of this plant mixed with syrup of buckthorn, is reckoned an effectual hydragogue. See Med. Ed. Edinb. vol. v. art. 8.

The root of this plant is recommended by Brookes as a remedy for the tooth-ach.

IRIS is also a name given by some authors to a peculiar species of spring crystal, remarkable for its giving the rainbow colours in reflection. This, however, being a property more or less found in all the kinds of spring crystal, and these much resembling one another, it became applied to spring crystal in general; and *iris*, instead of being the name of a peculiar species, was understood as a synonymous term for common crystal.

IRIS marina, the sea-rainbow. This elegant appearance is generally seen after a violent storm, in which the sea-water has been in vast emotions. The celestial rainbow has great advantage over the marine one in the brightness and variety of the colours, and in their distinctness

wise from the other; for in the sea-rainbow there are scarce any other colours than a dusky yellow on the part toward the sun, and a pale green on the opposite side. The other colours are not so bright or so diffused as to be well determined, but the sea-rainbows are more frequent and more numerous than the others. It is not uncommon to see twenty or thirty of them at a time at noon-day. *Observe, for Affe. p. 292.*

IRISH TERMS. See TERMS.

IRON, in Natural History, a hard, fusible, and malleable metal, of a greyish colour, of great use in the affairs of life.

Iron, like other metals, is said to consist of earth, *PHLOGISTON*, and a metallic or mercurial principle. This metal has, next to *COPPER*, the greatest tenacity of parts: an *iron-wire*, the diameter of which is $\frac{1}{16}$ of an inch, being capable of sustaining 450 lb. without being broken.

It is the lightest of all metals, except tin, being between seven and eight times specifically heavier than water. See *SPECIFIC GRAVITY*. It is also the hardest, most elastic, and, except *PLATINA*, and *MANGANESE*, the most difficult to melt, of all metallic substances.

Though *iron* grows red-hot much sooner than any other metal, it is not fusible by the heat of ordinary furnaces, nor without an intense white heat. When perfectly malleable, it is said not to be fusible at all, without additions, or the immediate contact of the burning fuel; and when melted, to lose its malleability: but M. Reaumur found, that forged *iron*, which could not be made to melt in a crucible without addition, was brought into fusion by surrounding it with *GYPHUM* or plaster of Paris; and Dr. Lewis found that *iron*, thus melted, proved very malleable, though some have thought that forged *iron*, brought into fusion, is of the same nature with common cast *iron*. *Iron* expands the least of the metals by heat; and in the act of fusion, instead of continuing to expand, like the other metals, it shrinks; and in its return to a consistent state, instead of shrinking, like the other metals, it expands or dilates into a large volume; and one of the marks of this dilatation is, the convexity of its surface, in circumstances wherein that of other metals is depressed. This property of *iron*, first discovered by M. Reaumur, excellently fits it for receiving impressions from moulds: but Dr. Lewis observes, that *platina* seems to destroy this power in *iron*. He also observes, that *platina*, melted with cast *iron*, contributes to render it tough, probably by throwing out and consuming that sulphureous matter, to which the brittleness of this kind of *iron* is chiefly owing, and which is separated in the process by which *iron* is made malleable: and, therefore, he conjectures, that *platina*, for certain purposes, may prove a valuable addition to this most useful metal, to which the workmen cannot communicate the hardness that is often required, without impairing at the same time brittleness and intractability. *Iron*, exposed to a white heat insufficient for its fusion, is calcined first into blackish scales; and afterwards into a dark reddish powder, called *canceris marris astringens*, which is nothing but the proper earth of *iron*, deprived of the greatest part of its phlogiston by calcination. When strongly heated, the surface of *iron* appears covered with a soft vitreous matter, like varnish; in this state, pieces of it cohere and on being hammered together, weld or unite without discovering a junction. As *iron* is the only metal which exhibits this appearance in the fire, it is likewise the only one capable of being welded. *Iron* heated as much as possible, or till it becomes of a shining white colour, and is just beginning to fuse, has the appearance of a combustible body; penetrated by a bright and vivid flame, and the inflammable principle of this metal thus heated, really burns in a sensible manner: a number of shining sparks floating out from it, and burning with a kind of decrepitation. *Iron* appears to be a combustible substance, from the great loss or waste of quantity observable in it, when exposed to a red, and especially to a white heat; and this consumption is excited and maintained like that of other combustible substances, by contact of air.

The sparks produced by the collision of steel with *FLINT*, appear to be globular particles of *iron*, which have been fused, and imperfectly fossilized or vitrified. The ignition, light, and fusion of the sparks, are occasioned by the heat excited by the combustion of their own inflammable matter, and continued in these particles during their passage through the air, and not merely by the heat communicated by the collision; for by an experiment of Mr. Haulbeck, it appears, that these sparks struck by collision, are not vitrified, that is, they are not ignited, and do not degenerate in an exhausted receiver; the air being necessary to maintain and excite their degradation and combustion. *Iron*, like other calcinable metals, acquires an increase of weight by calcina-

tion; and, by complete calcination, it is said to receive an augmentation of one third of its weight. *Iron* may be softened by heating it often in the fire, hammering it, and letting it cool of itself; and it is hardened by extinguishing it in water.

It may be rendered white by cooling it in fat ammoniac and quicklime. The strongest temper of *iron* is said to be that which it takes in the juice of earthworms.

The surface of *iron* is quickly corroded by moist air, and soon converted into a reddish yellow rust, or calx, deprived of all its phlogiston, and which cannot recover its metallic properties, without being again combined with its inflammable principle. Many methods have been used to preserve *iron* uncorrupted from rust; as animal tarry oil, boiled oil mixed with melted lead, &c. Homberg's salve for this purpose, consists of two pounds of hog's lard, an ounce of camphor, and as much black lead as will render the mixture of an *iron* colour: when this is used, the *iron* must be previously heated. M. Reaumur has discovered a better composition for this purpose: it is oil, impregnated by being exposed to the air in flat shallow vessels, so as just to cover the bottom, mixed with a solution of copal in spirit of wine; this forms an elegant hard varnish, which, rubbed on polished *iron*, made a little hotter than the hand can bear, will cover it with a solid, thin, transparent coat, without any injury to its colour or appearance. *Iron* is soluble in all acids, from which it precipitates all the common metallic bodies except zinc, and the semi-metals, regulus of cobalt and nickel; with the marine acid it yields a yellow; with the nitrous, a dark red, forming with these acids, separately or conjointly, salts with metallic bases, of a deliquescent nature, and with the vitriolic, a pale green solution, that forms a vitriolic salt with a metallic base, exsiccated by evaporation and cooling into green rhomboidal crystals, and which is changed to an inky blackness by the addition of a small quantity of galls, and by most of the other vegetable astringents; and to a reddish or purple, by a mixture of astringents with a minute proportion of any alkaline salt. Each of these acids deprives the *iron*, in the solution, of a considerable part of its phlogiston, or inflammable principle. During the solution in vitriolic acid, an inflammable vapour arises; which is permanent and elastic, and which has a great analogy to the inflammable *DUMPS* in mines. All the solutions of *iron*, by whatever acid effected, on the addition of a lixivium of alkaline salts that have been calcined and fully impregnated with animal coals, are changed to a deep blue, and on standing deposit the *iron* in form of a powder of the same colour. By these characters, a small minute portion of *iron* may be discovered in liquors. *Iron* has a greater affinity than any other metal with sulphur; and, therefore, may be employed to separate most metals from sulphur by fusion; and sulphur, thus united with *iron*, considerably augments its fusibility. If a bar of *iron* be heated till it becomes white, and a roll of sulphur be applied to one of its extremities thus heated, the sulphur uniting with the *iron*, makes it fuse so as to run down in red-hot drops. See *ARTIFICIAL FERTILIZERS*.

Iron has a great conformity with copper; and the two are not easily separated, when soldered together; whence arises that uncommon friendship which the poets teach between Mars and Venus.

Gold is also particularly disposed to unite with *iron*, of which, if the *iron* be pure, it differs twice or thrice its own weight in a degree of heat far less than that in which *iron* melts. In virtue of this property, gold proves an excellent solder for the finer kinds of steel instruments; a small thin plate of gold being pressed round the parts to be joined, the gold is made to melt by a blow-pipe, and strongly united together. *Iron* and steel, in very small proportions, render gold hard and eager; some of these mixtures are of such a degree of hardness and cleaviness, as admit them for receiving a fine edge, and it is said they have been formed into razors. For the method of gilding *iron*, see *GILDING*.

Iron is dissolved by all the metals made fluid by sufficient heat, except lead, on which it floats distinct, as oil upon water. Among the semi-metallic bodies, it is active to any union with mercury; no method has been hitherto discovered of amalgamating *iron*; though quicksilver, in certain circumstances, seems in some small degree to act upon it: a plate of tough *iron*, kept immersed in mercury for some days, becomes brittle; and mercury has been observed to adhere to, and coat the heads of *iron* pellets used in saturating certain amalgams with saline liquors. *Iron* filings may be amalgamated with mercury when the solution of green vitriol is added. See *AMALGAMATION of IRON*. For the affinities of *iron* with different substances, see *TABLE of AFFINITY*.

It has a great conformity also with the loadstone, being attracted by magnets. Robault observes that it is itself an imperfect loadstone; and that if it be a long time exposed in a certain situation, it becomes a real loadstone; and mentions the *iron* in the steeple of Notre Dame at Chartres as an instance.

By this property, it may be discovered in mixtures, where by other methods it could scarcely be perceived, and may be even separated when it is only interspersed betwixt other bodies, and not adherent to them. It preserves this property, although it be alloyed with some other metals. However, Gellert affirms, that this quality is destroyed by alloying *iron* with regulus of antimony.

It is observable, that several of the hard ores of *iron*, which are not affected in the least by the magnet in their natural state, are vigorously attracted by it when moderately roasted, though without the contact of any inflammable, and without seeming to lose any sulphureous matter; and that the calces of *iron*, by slight roasting with inflammable additions, are made to obey the loadstone, and revived into their metallic form, each particle appearing now to be perfect *iron*, whilst the calces of other metals are in no degree revived without being brought into fusion.

The several calces of *iron*, fused with large proportions of vitreous matters, impart different shades of yellow, reddish, green, and blue: and the colour, says Dr. Lewis, seems to be influenced more by the degree and continuance of the fire, and other circumstances in the process, than by the particular manner in which the *iron* is prepared.

Moreover, *iron* is capable of being combined either by fusion, or by cementation, with a more abundant quantity of phlogiston; and of being thus converted into a more perfect *iron*, called *steel*, which is capable of acquiring, by sudden cooling or tempering, a very great hardness, that renders it useful for many necessary purposes.

It would scarce have been believed, till experiments confirmed it, that *iron* makes a part of almost all sorts of substances. So that it is truly an universal metal, being found in all the mineral earths and flowers that have been examined, in the ores of all other metals, and even in the ashes of all vegetables and animals. Mr. Groffroy attempting to produce *iron* by chemistry out of several ingredients, into which it may be decomposed, wanted first to find such as in themselves contained no *iron*. He found that the ashes of all vegetable bodies whatever, contained more or less of that metal; and Mr. Lemery afterwards, in his analysis of honey, found *iron* in the calcined caput mortuum of that substance, many particles of it adhering to a knife that had been touched on a magnet.

This had much puzzled the thoughts of the chemists, when Mr. Lemery at length attempted to account for it in this manner. All earth is impregnated with a ferruginous and vitriolic matter, and this therefore must be received into the roots of plants in their growth, and make a part of their substances. It is however, in too small a quantity, and in particles too much diffused, to show itself in the stalks or leaves of the plant; but when the whole has been calcined, the fire collecting together its separated particles, they then form small masses which act as *iron*, and apply themselves to the magnet.

Besides, particles of *iron* are discovered by the magnet, not only in all vegetable ashes, but in animal ones; the ashes of eel have been found by the younger Lemery to contain also *iron* in as large a proportion as those of honey and of vegetables.

To try whether these particles attracted by the magnet in the ashes of vegetables were really *iron*, this author collected a small quantity of them together by means of a knife touched on the magnet, and exposing them to the focus of the great burning glass belonging to the then duke of Orleans, they were found to be melted by that heat in the same manner as common *iron*, and to be attended with all the same circumstances in the several states of fusion and diffipation. It sparkled greatly while soft, and finally was reduced to a ferruginous earth or bole, in all respects the same with that separated by the same means from filings of *iron*, or from the magnet. When this matter is thus proved to be real *iron*, the doubt how it is able to get into the minute vessels of plants, is cleared, by considering that *iron* is not only present in all earth, but is also very easily dissolved by all sorts of salts, and takes different forms with every one, according to its peculiar nature. When it is found in earths which contain an acid analogous to that of vitriol, sulphur, or alum, it becomes converted into a salt known by the name of vitriol; and what objection can there be against the supposing that this salt, when dissolved in a sufficient quan-

city of water, is received into the vessels of plants growing in the earth where it abounds; and we cannot doubt the diffusibility of the particles of *iron* in the state of this salt, being great enough to make it capable of passing even into the most minute vessels of plants, when we consider that a grain of vitriol dissolved in nine thousand times its own weight of water, is capable of giving colour to the whole, and with it a sensible taste of the metal from which it had its origin.

The specific gravity of *iron* has been by some supposed to be a reason against the believing its ascent in the vessels of plants; but this appears of no weight, when we consider that all flowers are found, on a chemical analysis, to contain earth, and that earth is heavier than *iron* in the state of vitriol; and that the metals in the state of vitriols, do often rise in vapour, and that without any great heat, is plain from this experiment, that if blue, green, and white vitriol be put together into a box, and covered down, the natural evaporation of each falling confusively on the others, will change the colour of every one on their upper surface, while that which touches the bottom of the box remains unaltered. If vitriol be put into an earthen vessel, and water poured on it in small quantity only to moisten it, the *iron* loaded with its acids, will be found in a little time to ascend up the sides of the pot to the top. This is a second proof that *iron* in the state of vitriol is to be raised or sublimed with great ease. There is, however, besides these, yet another more convincing.

When spirit of nitre is poured upon filings of *iron*, there arises an ebullition attended with so great heat that the hand can scarcely be held upon the outside of the vessel. After the ebullition the liquor becomes red, and greatly loaded with the dissolved *iron*. If oil of tartar be added to this liquor, there is raised a moderate ebullition, and the mixture swells greatly. After this there are found a number of branches very beautifully arranged on the sides of the vessel, and these continue to form themselves under the eye, while there is no fermentation nor ebullition in the liquor. These curious figures at length cover the whole surface of the vessel, and rising over the rim of it, fall on the outside, and cover that also. This beautiful vegetation may be varied a great many ways by the different proportions of the ingredients; but in every process it shows how very easily *iron* may be made to ascend upwards, and that to great heights; and when we consider the power of the heat of the sun, and of the fusion of the roots of plants, which are in a manner so many syphons acting together upon the juices of an earth, among which there are particles of *iron* thus dissolved; we are not to wonder that *iron* is conveyed into the vessels of the plant, or found afterwards in its ashes. The wonder would be that there should be any vegetable ashes which did not afford *iron*, but that does not appear yet to have been found in regard to any. Mem. Acad. Par. 1706.

The qualities of *iron*, with regard to hardness, brittleness, malleability, &c. are different according to the nature of the ore from which it is obtained, and the operation it has undergone. The *iron* run from some of the German ores, when forged only to a certain point, is found to be a good steel; whilst that of many others, taken in the same intermediate state, betwixt cast and completely forged *iron*, cannot be worked either as steel or *iron*. The Swedish, and some of our own ores, yield an excellent tough *iron*; whilst others give a brittle metal, that cannot by any forging be made perfectly malleable, and hence employed only for some kinds of nails and heavy works. The inferior ores are said to be meliorated by mixing two or three different sorts together. The Swedish *iron* has generally been preferred on many accounts, and particularly for making of steel; but the English *iron*, properly manufactured, has been found not inferior to it. The German *iron*, commonly called among us, *Dart-squares*, because it is brought hither from Dort, and wrought into bars of three quarters of an inch square, is a coarse *iron*, and only fit for ordinary uses. That sort which is used for the making of wire, is the softest and toughest of all, and acquires these qualities from being refined to a higher degree than is necessary for ordinary purposes.

Generally speaking, the best *iron* is that which is softest and toughest, and which, when it breaks, is of an even greyish colour, without any glittering specks, or any flaws or divisions like those seen in broken antimony.

IRON, bar. See BARS OF IRON and ANCHOR.

IRON, cast, is that which is run from the ore, and which, on account of a mixture of crude earth, not reduced to a metallic form, proves hard, but as generally not to yield in the least to the file or chisel; and brittle, both whilst cold and when ignited. When cast into thin plates, it cracks on being hastily cooled, like glass; and

when broke, appears of a dull white colour, approaching to that of unpolished silver, and of a smooth uniform texture, composed of plates laid close together, as scarce to be distinguishable, even by a microscope. The more impure sorts are less hard to the file, but not less brittle under the hammer: their colour is much darker, and their texture often granulated. When they are melted, a quantity of glassy scoria rises on the surface, and leaves the remaining metal pure and white like the foregoing sort. Pure cast-iron, surrounded with animal ashes, and exposed to a fire not sufficient to melt it, becomes by degrees so soft, that utensils or ornaments made of it may be easily cut and filed. During this cementation, it undergoes several remarkable changes, observed by M. Reaumur, and rectified by Dr. Lewis in his notes to Newmann's Chemistry, p. 79.

Iron, forged, is produced from cast-iron, heated till it is ready to melt, and compressed by repeated blows of large hammers, by which a quantity of vitreous matter is forced out and thrown off; its parts are more regularly arranged; the plates rendered smaller, and more distinct, by degrees changed into grains, and at length into fibres. Fine plates regularly arranged, small grains or fibres like those which appear on the fracture of wood, are marks of tough iron, provided it be not splintered; but large and irregular plates iron is universally short and brittle, and the colour of the fracture is usually whitish, and considerably bright. Pure cast-iron is malleable both when cold and hot, though not with equal facility: the more it is heated, it extends the more easily, and is less liable to crack. Some sorts of iron, though malleable when cold, prove entirely brittle if heated red; others are brittle when cold, and malleable only whilst ignited. The former are called by the workmen, *red-hot iron*, or *red bars*; the latter, *cold bars*, or *white-hot iron*. The impurity of the first is supposed to be owing to an admixture of sulphur; that of the second proceeds wholly from a want of sufficient forging. Forged iron is a little heavier than the cast, in the proportion of about 7½ to 7. It fortifies much more in the fire, and does not melt without additions, or the immediate contact of the fuel: the sublimance, says M. Reaumur, that fusion cast iron by cementation, increase the softness of the forged to a certain point; but beyond this, the operation renders it harder and more brittle than at first. See Dr. Lewis, &c. viii. supra.

Square and flat bars of iron are sometimes twisted, for ornaments: the manner of doing which is this: after the bar is square, or flat-forged, they give it a flame-heat, or if the work be small, only a blood-red heat; in which state it is easy to twist it about as much or as little as they please, with the tongs, vice, or the like.

The several heats which furnish give their iron work are, 1. A quaking or welding heat, which is used when they double up their iron, or weld two pieces of iron together, end to end. 2. A flame or white heat, which is used when the iron has not its form and size, but must be forged into both. 3. A blood-red heat, which is used when the iron has already its form and size, but wants a little hammering to smooth and fit it for the file—if the iron be made too hot, it will sometimes red-heat, i. e. break or crackle under the hammer while it is working between hot and cold.

We have a great number of iron works in most parts of England, and in Wales; those in the forest of Dean, in Gloucestershire, are in most repute.

The ore is there found in great abundance, differing much in colour, weight, and goodness. The best, called *Irish ore*, is of a bluish colour, very ponderous, and full of little shining specks, like grains of silver: this affords the greatest quantity of iron; but, being melted alone, it produces a metal very short and brittle, and therefore not fit for common use. For the remedying whereof, the workmen make use of another sort of material, termed *clinker*, which is nothing but the refuse of the ore, after the metal has been extracted; and which, being mingled with the other, in a due quantity, gives it that excellent temper of toughness, which causes this iron to be preferred before any brought from foreign parts.

It is asserted by a person conversant with the manufacture of iron, that if a sufficient quantity of this clinker were carried to the iron-works in any other part of the kingdom, and made use of instead of the lime-stone, the iron produced would be nearly, if not equally, as good as that of the forest of Dean. The same writer observes that in Staffordshire, and various parts of Yorkshire, where their iron is but of an indifferent quality, the matter made use of by way of flux, was generally unburnt lime-stone, which he thinks by no means proper for the purpose: in Sussex they use a certain fossil, com-

posed of a congeries of different shells of fishes, slightly bound together by a sort of reddish earth, not unlike some kinds of iron ore, called *grey*; which, he says, is a good flux, and produces a metal of excellent quality. Horne's Essay on Iron and Steel, p. 56, &c. But to return to the account of the manufacture of iron in the forest of Dean, which is similar to that pursued in other parts of the kingdom.—After they have provided the ore, their first work is to calcine it, which is done in kilns, much after the fashion of our ordinary lime-kilns: these they fill up to the top with coal and ore, stratum super stratum, that is, one layer upon another: and so putting fire to the bottom, they let it burn till the coal be wasted, and then renew the kilns with fresh ore and coal, in the same manner as before. This is done without fusion of the metal, and serves to consume the most drossy part of the ore, and to make it brittle; supplying the heating and washing which are used in other metals.

From hence they carry it to be melted to their furnaces, which are built of brick or stone, and are about twenty-four feet square on the outside, and near thirty feet in height within; not above eight or ten feet over where widest, which is about the middle: the top and bottom having a narrow compass, much like the shape of an egg. Behind the furnace are fixed two huge pair of bellows, the noses of which meet at a little hole near the bottom: these are compressed together by certain buttons, placed on the axis of a very large wheel, which is turned about by water, in the manner of an over-shot mill. As soon as these buttons are slid off, the bellows are raised again by the counterpoise of weights, whereby they are made to play alternately, the one giving its blast whilst the other is rising.

As first they fill the furnace with ore and clinker, intermixed with fuel, which in these works is always of charcoal, laying them hollow at the bottom, that they may more easily take fire; but after they are once kindled, the materials run together into a hard cake or lump, which is sustained by the fashion of the furnace; and through this the metal, as it melts, trickles down into the receivers set at the bottom, where there is a passage open, by which the men take away the scum and dross, and let out the metal as they see occasion. Before the mouth of the furnace there lies a great bed of sand, wherein they make furrows of the shape into which they would have their iron cast. As soon as the receivers are full, they let in the metal, which is made so very fluid by the violence of the fire, that it not only runs to a considerable distance, but stands afterwards boiling for a good while.

For the backs of chimneys, hearths of ovens, or the like, they take the melted metal out of the receivers in great ladles, and pour it into moulds of fine sand.

When the furnaces are once at work, they keep them constantly employed for many months together, never suffering the fire to slacken night or day, but still supplying the wasting of the fuel, and other materials, with fresh poured in at the top: charcoal is used altogether in this work; sea-coal will scarcely do. See IRON-ORE and FURNACE.

From these furnaces the workmen bring their *sear* and *pipe* of iron, as they call them, to their forges, one of which they call the *FINERY*, and the other the *CHAFERY*, where they are wrought into bars. Phil. Trans. N° 137. Abr. vol. ii. p. 536.

IRON, cast as upon. Any Spanish, Spruce, and Swedish iron imported in any other ship or vessel than such as is English built, and of which the master, and at least three-fourths of the mariners are English, pays on importation, 2l. 17s. 10½d. the ton, and draws back on exportation, 2l. 14s. 6½d. the same imported in English-built ships, and so navigated, to pay on importation, 2l. 8s. 6½d. the ton, and draw back on exportation, 2l. 5s. 2½d. Iron slit or hammered into rods, commonly known by the name of *rod-iron*, pays on importation, 8s. 6½d. the hundred wt. and draws back on exportation, 8s. 12½d. Ditto from Ireland, pays 3s. 10½d. and draws back, 3s. 4½d. Iron drawn or hammered less than three-fourths of an inch square, pays on importation 8s. 6½d. the hundred wt. and draws back on exportation, 8s. 12½d. Unwrought iron of Ireland, pays on importation, 1l. 6s. 11½d. the ton, and draws back on exportation, 1l. 3s. 7½d. Unwrought iron of all other places, not otherwise rated, imported in British ships, pays on importation, 2l. 8s. 6½d. the ton, and draws back on exportation, 2l. 5s. 2½d. and in foreign ships, pays on importation, 2l. 17s. 10½d. and draws back on exportation, 2l. 14s. 6½d. Iron-wares manufactured, not otherwise rated, or not prohibited by law, pay per hundred weight on importation, 12s. 4½d. and draw back on exportation

11s. 5¹/₂d. Iron-ore the ton, pays on importation 2s. 4¹/₂d. and draws back on exportation, 2s. 5¹/₂d. Old 100
 bushels, broken, and cast iron, pays on importation, the ton, 11s. 11¹/₂d. and draws back on exportation, 10s.

9 3¹/₂d. Backs for chimnies, small, the piece, pay on importation, 2s. 4¹/₂d. and draw back on exportation 100

2s. 4¹/₂d. Backs for chimnies, large, the piece, pay on importation, 4s. 9¹/₂d. and draw back on exportation, 4s. 5¹/₂d. Bands for kettles, the hundred wt. pay on importation, 11s. 4¹/₂d. and draw back on exportation, 11s. 5¹/₂d.

Fire irons, the gross, pay on importation, 11s. 11¹/₂d. and draw back on exportation, 11s. 8¹/₂d.

More for every hundred weight on importation, 4s. 8¹/₂d. and draw back on exportation, 4s. 8¹/₂d.

Hoops the hundred wt. pay on importation, 9s. 9¹/₂d. and draw back on exportation, 9s. 2¹/₂d.

Stoves, the piece, pay on importation, 10s. 3d. and draw back on exportation, 10s. 10¹/₂d.

More for every hundred weight on importation, 4s. 8¹/₂d. and draw back the same. Iron Kettles, the piece, pay 11s. 2¹/₂d. and draw back, on exportation, the same; and besides for every hundred weight on importation, 7s. 8¹/₂d. and draw back on exportation, 6s. 9d.

Pig, or bar-iron, from the British plantations in America, is imported free; but all such iron must be stamped with a mark, denoting the colony, or place where it was made, and a certificate produced of the oath of the exporter, signed by two of the principal officers of such colony; and the master, or commanding officer of the ship, or vessel, importing such iron, must make oath, that the iron is imported, in the same way that mentioned in the certificate. See CROC. H. C. 29.

IRON. In *Medicine*, is said to have greater virtues than any of the other metals, which is not to be wondered at, as being the only one that is in a manner soluble in the human body. All the other metals, whether hard or soft, poisonous or salutary, may even fluid mercury itself, swallowed in their crude state, pass out of the body again unaltered; but this is not the case with iron, its crude filings are often taken as a medicine, and are always so much acted upon by their juices, as to produce considerable effects. It is so easily wrought upon out of the body also by fire, and by different menstruums, that it becomes an aperient or astringent, as it is differently treated; and is, under proper management, greatly superior to all other medicines in chronic cases.

Its virtues internally were not unknown to the ancients: Dioscorides attributes both an astringency and aperient to it, and prescribes it in hemorrhages. He also recommends its rust, or *cruci martis*, in suppurations of the menies; though he on the other hand prescribes wine or water, in which red-hot iron had been quenched, as an astringent in dysenteries, diarrhoeas, and weakness of the stomach.

The great medicinal virtue of iron is caused by its tonic and strengthening qualities. It produces a slight and gentle irritation of the fibres, the effect of which is to confluence the sensible organic parts upon which it acts, and to increase their force and elasticity. Iron particularly acts upon the fibres, and the vessels of the stomach and intestines; hence it produces excellent effects in all diseases which proceed from laxity and inactivity of the digestive organs. Such are costiveness, bad digestion, accompanied with diarrhoea, flatulency, flaccid colic, &c. &c. in diseases which proceed from the former, as many hysterical, hypochondriacal, melancholic affections, intermittent fevers, tertians and quartans, &c. In those cases iron quickens the circulation and raises the pulse; renders the blood more florid, and as it were expands and rarefies the juices, promoting, when they are deficient, and restraining, when immoderate, the secretions that are made from the blood, as perspiration, urine, and the menses purgations. By the same corroborating power, which renders it serviceable in promoting efficient, and restraining redundant discharges, where the suppression or flux arises from debility and relaxation, it increases on the contrary, fluxes, and confirms obstructions, when they proceed from tension, rigidity, or spasmodic contractions of the vessels. Where either the circulation is quick, or the habit plethoric, by increasing the velocity of the blood, and the plethoric symptoms, it produces heaviness, distention, vague heats and flushings, of bloodless more dangerous fevers or inflammations, or bursts some of the over-distended small vessels. In some constitutions, where iron is proper and salutary, particularly in hysterical and hypochondriacal

cases, and where the stomach is very weak, it is apt at first to occasion great sickness and perturbation: to remedy these inconveniences, Sydenham advises to begin with very small doses, and to administer it for a while at bed-time, in conjunction with a slight opiate. In other circumstances, it is commonly taken in the morning and afternoon, and moderate exercise used to promote its action. In all cases the dose should be small and repeated: a grain, or half a grain of the metal dissolved or in a soluble state, is generally a sufficient dose. Its effects are known by mororous eruptions, and by the alvine faces being tinged of a black colour.

Stahl, and several other modern chemists and physicians acknowledge only the tonic and strengthening qualities of iron. The cases in which iron has produced a refreshing and aperient effect are those, in which the obstructions, and the defect of secretion and excretion, have proceeded from weakness and relaxation of the fibres and of the vessels rather than from a crassitude of humours, as in the chlorosis, in some kinds of jaundice, and other diseases of the same sort. The preparations of iron in more frequent use at present are, 1. the crude filings reduced to an impalpable powder: this is an excellent form for administering iron in female disorders, in which the body is weak, languid, and full of acridities: the dose of the filings is from two or three grains to a scruple or more. 2. *Mars fuscum*, which is the filings candied with sugar, by dissolving two parts of fine sugar in water, and boiling it down to a sandy consistence, and adding by little and little, one part of the cleaned filings in a kettle over a gentle fire; the vessel being continually shaken, that the filings may be cruised over with the sugar. In order to prevent the mixture from running into lumps, a little starch is previously mixed with the sugar, in the proportion of a dram to a pound. 3. *Linasure Martis preparata*, or *chalybis rubeo preparata*, is formed by moistening the filings with vinegar or water, and exposing them to a moist air, or occasionally moistening them with oil, which soon change in great part into rust; this rust may be separated from the uncorroded part, by grinding and washing over the finer powder with water. This is given in the same dose as the crude filings. 4. *Mars fuscum*, prepared by mixing iron filings with twice their weight of flower of brimstone, and as much water as will make them into a paste, which in a few hours swell up, and is then pulverized, and put into a heated crucible to deglaze, and kept constantly stirring with an iron spatula, till it falls into a deep black powder: this powder urged longer in the fire, becomes red, and is called, 5. *Crocus Martis* *apertus et astringens*. 6. The salt or viscid of iron, called *SAL Martis*. 7. *Tinctura Martis cum Spiritu salis*. 8. *Flores Martiales*, or flowers of iron. These are commonly given in the form of a bolus, from three or four grains to twenty. A tincture made by digesting four ounces of the flowers in a pint of proof-spirit, is a sufficiently elegant chalybeate, and may be given in doses of a tea-spoonful. 9. *Lixivium Martis*. 10. *Exaltatum Martis*, is formed by insipulating solutions of iron in wine, or other vegetable acids, to the consistence of an extract.

11. *Mars solubilis*, or *chalybis tartarizata*, is obtained by grinding the filings of iron, with an equal weight of cryalls of tartar, forming the mixture into a mass with water, then pulverizing, and repeating the humectation and exsiccation alternately, till the whole falls into an impalpable powder. This elegant and useful chalybeate is given either in a solid or liquid form, from two or three grains to ten or more. It has been usually distinguished in the shops, by the name of its inventor, Dr. Williams. 12. *Mars solubilis alkalinizatus*, is prepared by calcining a mixture of iron filings and tartar in a crucible for some time with a red heat, and again calcining such part as cannot easily be reduced into fine powder. But alkaline solutions of iron are ill adapted for medicinal use, and are at present wholly neglected. Lewis Med. See CHALYBEATE, and *Alkaline* and *Chalybeate* WATERS.

IRON, for the bluing of, see BLUING.

IRON, for the expansion of, by heat, see HEAT and PYROMETER.

IRON Chalybeate. See CHALYBEATE.

IRON, for the refining of, see REFINING.

IRON, for the conversion of, into steel, see STEEL.

IRON Furnace. See FURNACE and IRON *supra*.

IRON, Harpings. See HARPING.

IRON-moulds, and spots of ink in linen, may be taken out by dipping the stained part in water, sprinkling it with a little of the powdered essential salt of wood-torrel, then rubbing on a pewter plate, and washing the spot out with warm water.

IRON-moulds, yellow lumps of earth or stone, found in chalk-pits, about the Chiltern, in Oxfordshire, and elsewhere, being in reality a kind of pyrites, or indigested iron ore.

IRON-ORE. It has been supposed that no iron is found in its metallic state; though a malleable native iron is mentioned by Wallerius; Linnæus; and Cartesius: and it is now known that native iron exists in many places; the most remarkable mass of this sort is that discovered in Siberia; which weighs 1600 pounds. It is of that species called *red-hot iron*, being malleable while cold, but brittle when hot. Kirwan *El. Min.* p. 270. Most of the minerals called *iron-ores*, have an earthy, rusty, yellowish or brownish appearance, which proceeds from the facility with which the true iron ores are decomposed. All earths and stones which are naturally yellow or red, and all those which acquire these colours by calcination, receive them from the ferruginous earth mixed with them. The yellow and red ochres consist almost solely of this earth; the black and heavy sands are also generally ferruginous. One of the richest *iron-ores* is a heavy stone, the surface of which, when newly broken, is red and bluish, and is exceedingly hard. A quintal of this ore, according to Crantz, affords from sixty to eighty pounds of the best iron by a single fusion. The *iron-ore* most commonly found, is a stone of the colour of rust, of an intermediate weight betwixt those of ores in general, and unmetalliferous stones. Blood-stones, or hematites, sanguine or red-chalk, and emery, are *iron-ores*: most of these substances require little calcination before they become capable of attraction by a magnet and solution in aqua fortis; but the iron obtained from them is of a bad quality. *Iron-ores* are of various forms: sometimes they are earths, sometimes stones, sometimes grains.

Molt ore require to be roasted previously to their fusion: some more slightly, and others with a more violent and long-continued fire; of the latter kind, are those which contain much sulphur, arsenic, or vitriolic acid; such as the black *iron-ore*, from which the Swedish iron is said to be obtained: of the former kind, are the ores called *lap-ores*, and others which, being in a calcined state, and containing little sulphurous matter, would, by a further calcination, be rendered less capable of being reduced to a metallic state. Ores differ from one another with regard to the facility of their fusion: the fusible ores are those which contain sulphur, arsenic, or are mixed with some fusible earth: the ores fusible with difficulty, are those which contain no mixture of other substance; such are most of the ores which contain iron in a state nearly metallic, and those which are mixed with some very refractory substance.

In the *iron works* in Staffordshire, after the ore is dug, before it be fit for the furnace, they burn or calcine it on the open ground with small charcoal, wood, or sea-coal, to make it break into small pieces, which will be done in three days. This they call annealing or fitting it for the furnace. See *IRON-works*.

Iron may be procured from its ore in a close vessel in the following manner: roast for a few minutes in a tell, placed under a muffle in a pretty strong fire, two centers of *iron-ore*, grossly powdered, that the volatile particles may be in part dissipated, and the ore softened in case it be too hard. When it has grown cold, beat it to a very fine powder, and roast it a second time in a stronger fire till it emits no fumes, then take it out of the fire.

Compose a flux of three parts of the common white flux, and one part of powdered glass, and add of sandifer and emul-dust of each one half part. Add to this flux three times the quantity of the roasted ore, and mix the whole very well together; then take a good crucible, well luted within, and put into it the ore mixed with the flux; cover it with common salt, and shut it close with a tile, and with lute applied to the joints. Put the common wind-furnace upon its bottom part, having a bed made of coal-dust; introduce into the furnace a small grate supported on its *iron bars*, and a flue upon it wherein the crucible may stand; surround the whole with hard coals, not very large, and light them at top. Make the fire very strong, and continue to add fresh fuel, that the vessel may never be naked at top. When the fire has thus been continued in its full strength for an hour, take out the vessel, and strike on the floor where it stands, to collect all the particles of *iron* into a body; and when cold, break the vessel, and you will find the pure *iron*.

The fuel used in most parts of Europe for the smelting of ores of iron is charcoal, which produces an *iron* capable of being rendered malleable by forging, better than any other. However, lately in several works in England and Scotland, *iron-ore* has been smelted by means of pit-coal, previously reduced to cinders or cox, by a kind of calcination similar to the operation of converting wood into charcoal, by which the aqueous and sulphurous parts of the coal are expelled, while only the more fixed bituminous parts are left behind. In France uncalcined pit-coal has been tried, but without success. The use of *peat*, mixed with charcoal, and likewise by itself, has been introduced in some parts of England.

Mr. Mason informs us, that at Colebrook Dale, in Shropshire, Mr. Ford makes *iron* brittle or tough as he pleases, from *iron-ore* and coal, both got in the same date; there being cannon thus cast, so soft as to bear taring like wrought *iron*. Phil. Trans. N° 482. sect. 6.

IRON-SKEW, is applied to a ship or boat, when her bolts, nails, or spikes, are to be eaten with rust, that they make hollows in the planks, whereby the ship leaks.

IRON-WOOD, *ferocypin*, in Botany, a genus of the *pentandria monogamia* class. Its characters are, these: the emplantment of the flower is permanent, and is cut into five segments; the flower is bell-shaped, divided into five parts at the tum; it has five awl-shaped stamens, the length of the petal, terminated by single filaments; and a round germen, supporting an awl-shaped style, crowned by a single stigma; the germen afterwards becomes a roundish berry, having one cell, containing four seeds. There are two species, natives of the Cape of Good Hope. Linnæus enumerates eight.

The wood of these trees being very close and solid, has given occasion for this name being applied to them, it being so heavy as to sink in water: and the title of *iron-wood* having been applied to the wood, by the inhabitants of the countries where it grows, has occasioned the botanists to constitute a genus by this name. But as the characters of the plants have not been so well examined as could be wished, occasioned by their seldom flowering in Europe, it is very probable, that the plants which have been ranged under this genus, do not properly belong to it. Miller.

IRON-WORT, *sideritis*, *Conila*, in Botany, a genus of the *dynamia gymnospermia* class. Its characters are, these: the flower has an oblong tubulose emplantment, cut into five segments at the top; it is of the lip kind, of one petal, almost equal; the tube is cylindrical, the chaps oblong and taper; the upper lip is erect, and cut into two acute segments; the under lip is cut into three; the two side segments are acute, the middle round and emarginate; it has four stamens within the tube, two of which are as long as the tube; the other shorter; and a four pointed germen, supporting a slender style, a little longer than the stamens, crowned by two stigmas, the upper is cylindrical, concave and turn; the lower, short and membranaceous; the germen turns to four seeds, which ripen in the emplantment. There are eleven species in the Linnæan system.

The common *iron-wort* grows in Germany, Italy, and France; and flowers in June: the herb is used; it is said to be good for wounds and ruptures; and to be so drying, as to cure a *flux albus*.

IRON-WORK, in a Ship, denotes all the pieces of iron, of whatsoever figure or size, which are used in its construction: as bolts, boom-irons, which are composed of two rings nearly resembling the figure of 8, nails, spikes, chains and chain-plates, block-strops, cranks, brates, pintles, and goodings.

IRONY, derived from *αἴρων*, *disimulation*, in Oratory, a figure in speech, whereby we plainly intend something very different from what our words express; as when we seem to praise a person at a time when we evidently rally, and discommend him.

Quintilian calls this figure *ειρωνισμός*, *disimulation*, and *allegory*; and observes that it may be known by the manner of the pronunciation, or from the nature of the person, or the thing. The subjects of irony are vices and follies of all kinds; and it has thus been used by the most grave persons on proper occasions. Horace uses it so much as to acquire the name of *αἴρων*, or the *drill*. It was also used by the prophet Elijah, a King, xviii. 27. by Solomon, Ecclesi. xi. 9. and by our Saviour himself, Mark vii. 9.

IRRADIATION, signifies an emanation, or shooting out of rays, or subtle effluvia, from any body. See *EMANATION*, *RAY*, *EFFLUVIA*, and *QUALITY*.

IRRATIONAL Numbers, the same as *ard numbers*. See *Surd* and *NUMBERS*.

IRREATIONAL Quantities. See *RATIONAL Quantities*.

IRREDUCIBLE *case*, in Algebra, is used for that case of cubic equations where the root, according to Cardan's rule, appears under an impossible or imaginary form, yet is real. Thus is the equation, $x^3 - 90x = 1000$, the root, according to Cardan's rule will be $x = \sqrt[3]{50 + \sqrt{-24500}}$

+ $\sqrt[3]{50 - \sqrt{-24500}}$, which is an impossible expression, and yet one root is equal to 10; and the other two roots of the equation are also real. Algebraists, for two centuries, have in vain endeavoured to resolve this case, and bring it under a real form; and the question is not less famous among them than the squaring of the circle is among geometers.

It is to be observed, that as in some other cases of cubic equations, the value of the root, though rational, is found

found under an irrational or surd form; because the root in this case is compounded of two equal furds with contrary signs, which destroy each other; as if $x = 5 + \sqrt{5} + 5 - \sqrt{5}$; then $x = 10$. In like manner, in the *irrational* case, when the root is rational, there are two equal imaginary quantities, with contrary signs, joined to real quantities; so that the imaginary quantities destroy each other. Thus the expression $\sqrt{50 + \sqrt{-24500}} = 5 + \sqrt{-5}$; and $\sqrt{50 - \sqrt{-24500}} = 5 - \sqrt{-5}$. But $5 + \sqrt{-5} + 5 - \sqrt{-5} = 10$; the root of the proposed equation.

Dr. Wallis seems to have intended to show, that there is no case of cubic equations *irrationalis*, or *impracticabilis*, as he calls it, notwithstanding the common opinion to the contrary. Algebra, chap. 46, p. 179, 180. edit. 1684.

Thus in the equation $x^3 - 63x = 162$, where the value of the root, according to Cardan's rule, is $\sqrt[3]{81 + \sqrt{-2700}} + \sqrt[3]{81 - \sqrt{-2700}}$, the *diabolus* says, that the cubic root of $81 + \sqrt{-2700}$, may be extracted by another impossible binomial, viz. by $\sqrt[3]{4 + \sqrt{-3}}$; and in the same manner, that the cubic root of $81 - \sqrt{-2700}$ may be extracted, and is equal to $\sqrt[3]{4 - \sqrt{-3}}$; from whence he infers, that $\sqrt[3]{4 + \sqrt{-3}} + \sqrt[3]{4 - \sqrt{-3}} = 9$, is one of the roots of the equation proposed. And this is true. But those who will consult his Algebra, p. 169, 171, will find that the rule he gives is nothing but a trial, both in determining that part of the root which is without a radical sign, and that part which is within; and if the original equation had been such as to have its roots irrational, his trial would never have succeeded. Besides, it is certain, that the extracting the cubic root of $81 + \sqrt{-2700}$, is of the same degree of difficulty, as the extracting the root of the original equation $x^3 - 63x = 162$; and that both require the trisection of an angle for a perfect solution. See M. de Moivre in the Appendix to Simon Stevin's Algebra, p. 744. See Far Cardan's rule, for Cubic Equations.

Mr. Maister, chiefest baron of the exchequer, has lately deduced, by a long train of algebrical reasoning, from Sir Isaac Newton's celebrated binomial theorem, an infinite series, which will resolve this case, without any mention of either impossible, or negative quantities. In a schoolman, he computes his own solution with those of Dr. Wallis and Mr. De Moivre. Phil. Trans. vol. xviii. part i. art. 23.

IRREGULAR, something that deviates from the common forms or rules.

Thus we say, an *irregular fortification*, an *irregular building*, &c. See BUILDING, FORTIFICATION, BATHING, and PLACE.

IRREGULAR Figures, in Geometry, is that whose sides and angles are not equal. See REGULAR.

IRREGULARS, in Grammar, are such inflexions of words as vary from the general rule, or pattern.

IRREGULAR, among the *Calists*, is applied to a person who is unqualified for entering into orders, as being a bastard, maimed, &c. or to an ecclesiastic, who is interdicted, suspended, or censured, and by that means rendered incapable of holding a benefice, or discharging any of the sacred functions.

IRREGULAR Indies, are solids not terminated by equal and similar surfaces.

IRREGULAR, in the Art of Building, is applied not only to the parts of an edifice which deviate from the proportions established by antique monuments, and confirmed by architects; as when a Doric column is made nine modules high, or a Corinthian eleven; but also to the places and figures of buildings, where the angles and sides are made unequal, as in most of the ancient castles; where, without any necessity or confinement from the situation, they effected such irregularity. A column is also said to be *irregular*, not only when it deviates from the proportions of any of the five orders, but when its ornaments, whether in the fluted, or the capital, are absurd and ill chosen.

IRREGULAR Leap, in Astrology. See LEAP.

IRREGULARITIES in the Mind's Action. See MOOD.

IRREPLEVABLE Return. See RETURN.

IRREPLEVABLE, or IRREPLEVABLE, in Common Law, signifies what may not be repleaded, or set at large upon a facies.

IRRIGATION, *Irrigatio*, denotes the watering a meadow or garden.

IRRITABILITY, in Anatomy and Medicine, a term first invented by Giffon, and adopted by Dr. Haller to denote an essential property of all animal bodies, and which, he says, exists independently of and in contradistinction to *sensibility*. This ingenious author calls that part of the human body *irritable*, which becomes flaccid upon being touched; *very irritable*, if it contracts upon a

slight touch; and the contrary, if by a violent touch it contracts but little. He calls that a sensible part of the human body, which upon being touched transmits the impression of it to the soul; and in brutes, he calls those parts sensible, the irritation of which occasions evident signs of pain and disgust in the animal. On the contrary, he calls that insensible, which being burnt, tore, pricked, or cut till it is quite destroyed, occasions no sign of pain nor convulsion, nor any sort of change in the situation of the body. From the result of many cruel experiments he concludes, that the epidermis is insensible; that the skin is sensible in a greater degree than any other part of the body; that the fit and cellular membrane is insensible; and the muscular soft sensible, the sensibility of which he ascribes rather to the nerves than to the flesh itself. The tendons, he says, having no nerves disseminated to them, are insensible. The ligaments and capsules of the articulations are also concluded to be insensible; whereas Dr. Haller infers, that the sharp parts of the joint are not fenced in exceptuals of the joint, but in the skin, and in the nerves which creep upon its external surface. The bones are all insensible, says Dr. Haller, except the teeth; and likewise the marrow. Under his experiments the pericranium and pericranium, the dura and pia mater appeared insensible; and he infers, that the sensibility of the nerves is owing to the medulla, and not to the membranes. The arteries and veins are held insensible of little or no sensation, except the carotid, the lingual, temporal, pharyngeal, labial, thyroidal, and the aorta near the heart, the sensibility of which is ascribed to the nerves that accompany them. Sensibility is allowed to the internal membranes of the stomach, intestines, bladder, ureters, vagina, and womb, on account of their being of the same nature with the skin; the heart is also supposed to be sensible; but the lungs, liver, spleen, and kidneys are possessed of a very imperfect, if any sensation. The glands, having few nerves, are endowed with only an obscure sensibility. Some sensibility is allowed to the tunica choroides and the iris, though in a less degree than the retina; but none to the cornea. Dr. Haller concludes, in general, that the nerves alone are sensible of themselves, and that in proportion to the number of nerves apparently disseminated to particular parts, such parts possess a greater or less degree of sensibility. *Irritability*, according to Dr. Haller, is so different from sensibility, that the most irritable parts are not at all sensible, and *vice versa*. He discharges facts to prove this position, and also to demonstrate, that *irritability* does not depend upon the nerves, which are not irritable, but upon the original formation of the parts which are susceptible of it. *Irritability*, he says, is not proportioned to sensibility; in proof of which, he observes, that the intestines, though rather less sensible than the stomach, are more irritable; and that the heart is very irritable, though it has but a small degree of sensation.

Irritability, according to Dr. Haller, is the distinguishing characteristic between the muscular and cellular fibres; whence he determines the ligaments, pericranium, meninges of the brain, and all the membranes composed of the cellular substance, to be void of *irritability*. The tendons are *irritable*; and though he does not absolutely deny *irritability* to the arteries, yet his experiments on the aorta produced no contraction. The veins and excretory ducts are, in a small degree, *irritable*; and the gall-bladder, the ductus chole-dochus, the ureters and urethra are only affected by a very acrid corrosive; but the vesical vessels are considerably irritable. The glands and mucous sinuses, the uterus in quadrupeds, the human matrix and the genital are all *irritable*; as are also the muscles, particularly the diaphragm. The oesophagus, stomach, and intestines, are irritable; but of all the animal organs the heart is endowed with the greatest *irritability*. In general, there is nothing irritable in the animal body but the muscular fibres; and the vital parts are the most irritable. This power of motion, arising from irritations, is supposed to be different from all other properties of bodies, and probably resides in the glutinous mucus of the muscular fibres, altogether independently of the influence of the soul. The *irritability* of the muscles is said to be destroyed by drying of the fibres, coagulating of the fat, and more especially by the use of opium in living animals. The physiological system, of which an abstract has been now given, has been adopted and confirmed by Castel and Zimmermann; and also by Dr. Brocchius, who suggests, that *irritability*, as distinguished from sensibility, may depend upon a series of nerves different from such as serve either for voluntary motion or sensation. Haller's Diff. on the sensible and irritable Part of Animals, translated by Tissot paffim. Phil. Trans. vol. xix. art. 28. p. 240. This system has been commented by Mr. Le Cat, and particularly by Dr. Whitt in his Physiological Essay. Ed. ii.

ISABELLA, in *Conchyliology*, the name given by the French naturalists to the beautiful pale-brown voluta, so much esteemed in the Dutch cabinets.

ISAGON, in *Geometry*, is sometimes used for a figure consisting of equal angles.

ISAIAH, or the Prophet of **ISRAEL**, a prophetic book of the Old Testament. *Isaiah* is the first of the four greater prophets, the others three being Jeremiah, Ezekiel, and Daniel. This prophet was of royal blood; his father Amos being brother to Azariah, king of Judah. The five first chapters of his prophecy relate to the reign of Azariah; the vision in the sixth chapter happened in the time of Jotham; the next chapters, to the reign of Ahaz; and his prophecies under the reign of Ahaz, and those that were made under the reigns of Hezekiah and Manasseh, are related in the next chapters to the end. *Isaiah* foretold the deliverance of the Jews from their captivity in Babylon by Cyrus, one hundred years before it came to pass. But the most remarkable of his predictions are those concerning the Messiah, which describe not only his descent but all the remarkable circumstances of his life and death. The style of this prophet is noble, nervous, fullness, and florid, which he acquired by converse with men of the greatest abilities and eloquence: Grotius calls him the Demosthenes of the Hebrews. However the profoundness of his thoughts, the loftiness of his expressions, and the extent of his prophecy, render him one of the most difficult of all the prophets; and the commentaries that have been hitherto written on his prophecy fall short of a full explanation of it. Bishop Lowth's new translation, &c. published in 1758, throws considerable light on the composition and meaning of *Isaiah*.

ISAMBELUCIS, in *Natural History*, the name of a genus of fossils of the class of the *Strophomena*, but of the columnar, not the rhomboidal kind. See *Tab. of Fossils, Class 2*. The specimens of this genus consist of six bones, and two skulls or short ends; and all their sides being very nearly of the same breadth, they much resemble broken pieces of the columns of *Strophomena*.

The bodies of this genus, as well as the rest of the columnar *Isambelucis*, are subject to a longitudinal crack, which sometimes admitting a small quantity of clay, shapes it into the figure of an ear of grain. *Hist. Nat. de Foss. p. 121*. See the article *SELENITE*.

ISARUS, in *Zoology*, a name given by the ancients to the *Chamaeleon*.

ISATIS, in *Botany*. See *Woad*.

ISATIS, in *Zoology*. See *Lagopus*.

ISATODES, a word used by Hippocrates, and some other of the old writers, to express a greenish colour of the bile discovered in the stools, which resembles the colour of the herb *Isatis*, or *Isatis*. This was esteemed an indication of a highly degenerated bile.

ISCHEMON, in *Botany*, a name used by many authors for the graft called *grana nasuta*, *maius* graft, or *Ruissard*.

ISCHION was also a word used by the ancients to express any thing given as a remedy in hemorrhages, or other fluxes of blood, whether from wounds or otherwise.

ISCHANUM, in *Botany*, the name by which Linnaeus calls the *fibranth*, or *canari* hay. This makes a peculiar genus of plants of the *polygama monosa* class; the characters of which are these: it has male and hermaphrodite flowers, distinct from one another; the male flower is very small, and always stands upon the glume of the cup of the female flower; its cup is a bivalve glume, with no awns, and containing only one flower; the flower is another bivalve glume of the size of the cup, and without awns; the laminae are three short capillary filaments; and the anther simple; the hermaphrodite flower is larger; its cup is a large bivalve glume, placed within the common glume, and terminated by a twisted awn, or beard between each valve; the flower is a small double glume; the pistil consists of an oblong germin, and two reflex styles all the glumes of the cup, flower, &c. continue to surround and inclose the seed; and they never drop it out till forced from them, each containing one seed.

ISCHAS, in *Botany*, a name given by Clusius, and some others, to those species of *rubra* or *argentea*, which have tubercles or knobby-roots, and are called by others *argentea*.

ISCHENIA, *argentea*. In *Aqueduct*, anniversary sports celebrated at Olympia, in memory of Iphigenia, the grandson of Mercury and Hecyra; who, in a time of famine, devoted himself to be a sacrifice for his country, and was honoured with a monument near the Olympian flames.

ISCHADIC, *Ischadadic*, derived from *ischad*, or *ischad*, *ischad*, the hip, an epithet given by physicians to two veins of the foot, which terminate in the crural.

The first, called the *great ischadic*, is formed by ten little branches, proceeding from the toes, which, uniting together, pass by the moles of the calf of the leg.

The lesser *ischadic* is formed by several ramifications, proceeding from the skin and muscles, which encompass the articulation of the thigh.—They are also called *ischadic*.

ISCHIAS, *ISCHADICA* or *ISCHIATICA*. See *SCIATICA*. **ISCHIO-CAVERNEUX**, in *Anatomy*, a name given by Winslow, and other of the French anatomists, to a muscle of the penis, called also by some the *profundus* and *suberosus penis*, but now generally named, from its office, the *erector*.

ISCHIO-CAVERNEUX is also applied by the same authors to a muscle of the female pudenda, called by some the *musculus ischioidis* and *ischioidis magnifissimus*, and by Cowper and Albinus, from its office, the *erector ischioidis*.

ISCHIUM, or *Ischium*, derived from *ischos*, *robur*, strength, in *Anatomy*, the name of one of the bones of the hip; called also, *os coxae* and *os coxae*.

In the *ischium* is a deep cavity, called *cavitas acetabulum*, which receives the head of the thigh bone. This cavity is encompassed with a cartilaginous circle, which serves to strengthen the thigh.

The *ischium* is one of the ossa innominata of authors.—See *Tab. Anat. (Ossis)* fig. 3. lit. S. n. 19. fig. 13. lit. c. This is the lowest portion of the *os innominatum*, as also of the whole trunk. It is divided into the body, the tuberosity, and the ramus or branch.

The body of the *ischium* forms the lowest and greatest part of the acetabulum, and sends out an apophysis backward, called the spine of the *ischium*. The tuberosity is very thick, unequal, and turned downwards; and it is on this part that the whole body rests when we sit. It appears cartilaginous, because of the blood and hardened remains of the tendons. The whole convex portion of it is originally an apophysis, of which the marks are obliterated lower in some subjects, than in others; three muscular insertions may be distinguished in it.

The branch of the *ischium* is a kind of thin flat production, or apophysis, which ascends forward from the tuberosity of the curvature of the os pubis, and it is often covered in part by a continuation of the epiphysis of the tuberosity.

These three parts of the *ischium* taken together, form a large opening, which makes the greatest part of the foramen ovale. Three other passages are remarkable in this bone; one posterior, between the tuberosity and the spine, for the passage of the internal obturator muscle, which is a little cartilaginous, and divided into three or four superficial channels; one lateral, between the tuberosity and the acetabulum, for the passage of the external obturator muscle; and one anterior, at the edge of the acetabulum for ligaments. Winslow.

ISCHNAMBLUCIS, in *Natural History*, the name of a genus of fossils of the class of the *SELENITE*, but one of those which are of a columnar form, not of the common rhomboidal one. See *Tab. of Fossils, Class 2*. The word is derived from the Greek, *ischnos*, *thin*, *ambros*, *short* or *oblique*, and *nam*, a column, and expresses a body in form of a thin or flattened column, with obtuse ends. The bodies of this genus are of an octobulbar figure, consisting of six long planes and about two broken ends. The top and base planes are broader than the rest. The crack which runs through the whole length of bodies of this genus is often filled with clay, which spreads itself into the form of an ear of some grain; of this genus there are only four known species. Hill.

ISCHNOPHONIA, formed of *ischnos*, *thin*, and *phonia*, *voice*, a word used by some authors to express that weakness and distubance of the voice which attends persons in some diseases; more usually, however, it is understood to express a stammering or imperfection in the speech.

ISCHURIA, *ischuria* formed from *ischos*, *I*, *stop*, and *urine*, in *Physic*, a disease consisting in an entire suppression of urine.

It is occasioned by any thing which may obstruct the passages of the ureters, or the neck of the bladder, as *stone*, *musculus*, &c.—It may also arise from an obstruction of the nerves, which pass to the reins or bladder, as we see it does, in a palsy of the parts below the diaphragm.—The too great distention of the bladder may also produce the same effect, for the fibres being much lengthened, and consequently condensed, the firmness necessary for their contraction cannot get admittance; whence it is that persons, who have retained their urine a long time, find a great deal of difficulty in discharging it. See *SUPPRESSION of urine*.

ISCUSTOS, a word used by the writers of the middle ages as the name of a gem, but seeming to be only a corrupt way of spelling *albescent*. Albertus says it was of a yellowish colour, and found in Spain, and that its fibrous texture made it capable of being wrought into cloth, which when thrown into the fire, was not consumed, but only cleaned by burning. See *ALBESCENT*.

ISELASTICS, *Iseleus*, kind of games, or combats, celebrated in the cities of Greece and Asia, in the time of the Roman emperors.

The victors at these games had very considerable privileges conferred on them; after the example of Augustus, and the Athenians, who did the like to the conquerors at the Olympic, Pythian, and Isthmian games. They were crowned on the spot, immediately after their victory; had pensions allowed them; were furnished with provisions at the public cost; were carried home in triumph, and made to enter their cities through a breach in the walls; whence their appellation, from *iselaus*, to enter.

ISLA, *Isula*, feasts and sacrifices solemnized in honour of the goddess *Ila*.

The *Ila* were full of the most abominable impurities; and for that reason, those who were initiated into them were obliged to take an oath of secrecy. They held for nine days successively, but grew so scandalous, that the senate abolished them at Rome, under the consulate of Piso and Gabinius. They were re-established by Augustus, and the emperor Commodus himself assisted at them, appearing among the priests of that goddess with his head shaven, and carrying the *Amule*.

ISIAC TABLE, is one of the most considerable monuments of antiquity, discovered at Rome in 1539, and supported by the various figures in bas relief upon it, to represent the feasts of *Ila*, and other Egyptian deities. There have been various opinions as to the antiquity of this monument; some have supposed that it was carved long before the time when the Egyptians worshipped the figures of men and women. Others, among whom is bishop Warburton, apprehend, that it was made at Rome, by persons attached to the worship of *Ila*. Dr. Warburton considers it as one of the most modern of the Egyptian monuments, on account of the great mixture of hieroglyphic characters, which it bears.

ISIACI, priests of the goddess *Ila*.—Dioscorides tells us, that they bore a branch of sea-wormwood in their hands instead of olive. They sang the praises of the goddess twice a day, viz. at the rising of the sun, when they opened her temple; after which they begged alms the rest of the day, and returning at night, repeated their orisons, and flung up the temple.

Such was the life and office of the *Isiaci*; they never covered their feet with any thing but the thin bark of the plant papyrus, which occasioned Priapus and others to say they went bare-footed. They wore no garments but linen, because *Ila* was the first who taught mankind the culture of this commodity. See Diodorus Siculus, and Plutarch's *Ila* and *Osiris*.

ISINGLASS, a name given to Muscovy tale, and to *Ichthyocolle*, which see.

A strong glue is made of *Isinglass* dissolved in spirit of wine. See *GLUE* and *ICHTHYOCOLLE*.

ISINGLASS-FISH, the English name of the fish from which the drug called *ichthyola* or *isoplati* is made. It is a species of the *autipora* or *sturgeon*, and is distinguished by not having any of the tubercles which the body of the common *sturgeon* has. See *ACIPERES* and *HEROS*.

ISIR, or *Isis*, a name used by some of the chemical writers for an elixir.

ISIS, in *Mythology*, a goddess of the ancient Egyptians, worshipped by them and many other nations; *Ila* is reported by Diodorus Siculus to have invented many excellent medicines; and hence, *Ila* he, after she was received among the number of the deities, she was applied to for the cure of distempers; and frequently indicated remedies by dreams. Galen takes notice of some plasters which bear her name.

ISIS, in *Natural History*, a term used by Linnæus to express a genus of *ZOOPLYTES*, comprehending six different species.

ISKA, a name given by the ancients to a light kind of agaric, growing to the old stumps of the oak, hazel, and other trees. This being a very light kind of fuel, was used by the ancients in the manner of a cattery, as we have learned from the Indians to use moss or the down of mugwort leaves.

ISLAM. See *MAHOMEDAN*.

ISLAND, or *ISLE*, a tract of dry land encompassed with water; either with the sea, a river or lake. In which sense *Island* stands contradistinguished from *continent*, or *terra firma*.

Some conclude, that *Islands* are as ancient as the world, and, it is by no means probable, that the large *Islands*, far remote from the continent, are new, or that they either arose out of the sea, or were torn from the main land. Nor is it less certain, that there have been new *Islands* formed by the casting up of vast heaps of clay, mud, sand, &c. as that, for instance, of *Tringming*, in the province of Nampin in China; or by the violence of the sea, which has torn off large promontories from

the continent, as the ancients imagined Sicily, and even Great Britain to have been formed. It is also certain, that some have emerged above the waves, as *Santorini* formerly, and three other *Isles* near it lately; the last in 1707, which rose from the bottom of the sea, after an earthquake, that was supposed to have loosened it from its bed.

Several naturalists are of opinion, that *Islands* were formed at the deluge; others think they have been rent and separated from the continent by violent storms, inundations, and earthquakes. These last have observed that the *East-Indies*, which abound in *Islands* more than any other part of the world, are likewise more annoyed with earthquakes, tempests, lightnings, volcanos, &c. than any other part.

Varenus thinks most of these opinions true in some instances, and believes that there have been *Islands* produced each of these ways. St. Helena, Ascension, and other deep rocky *Islands*, he supposes to have become so, by the sea's overflowing their neighbouring champaigns. By the heaping up huge quantities of sand, and other terrestrial matters, he thinks the *Islands* of Zealand, Japan, &c. were formed. Samarra and Ceylon, and most of the *East-Indian Islands*, he rather thinks were rent off from the main land; and concludes, that the *Islands* of the Archipelago were formed in the same way; imagining it probable, that Deucalion's flood might contribute towards it.

The ancients had a notion, that *Delos*, and some few other *Islands* rose from the bottom of the sea, which, how fabulous matter it might appear, agrees very well with some later observations. Strabo takes notice, that the *Island* Theracia rose out of the *Ægean Sea* in his time, of which the mariners were eye-witnesses.

Floating-Islands: Historians are full of accounts of floating *Islands*; but the greater part of them are either false, or founded on exaggerations. What we generally see of this kind is no more than the concretion of the lighter and more viscous matter floating on the surface of water in calms, and with the roots of plants, forming conglomerates of different fibres, which not being fixed to the shore in any part, are blown about by the wind, and float on the surface. These are generally found in lakes, where they are confined from being carried too far; and from being broken by the agitation of the water. And in process of time some of them acquire a very considerable size. Seneca tells us of many of these floating *Islands* in Italy; and some later writers have described not a few of them in other places. But however true the histories of these might have been at the time when they were wrote, there remain very few proofs of their truth at this time, these *Islands* having either disappeared again, or been fixed to the sides, in some part, in such a manner as to have made a part of the shore. Piny tells us of a great *Island* which at one time loomed about the lake Catella, in the country of *Armenia*, which was discovered by the old Romans by an oracle; and Pomponius tells us, that in *Lydia* there were several *Islands* to loose in their foundations, that every little accident shook and removed them. Herodotus speaks also very largely of the lake *Chemmis* in *Egypt*. See *ASSURATIONS of the Earth*.

Geoplinander has written a Latin treatise expressly on *Islands*, *de Insulis*.

ISLANDS, Fortunate. See *FORTUNATE*.

ISLAND, Crystal. See *CRYSTAL*.

ISLAND-FISH, in the *Fish-trade*, a name given to the common con-fish when it has been caught and preserved in *Island*.

ISLERIANUS Isip, in *Natural History*, a name given by authors to a kind of blackish slate, very heavy, not very hard, and easily splitting into thin flakes. It is dug near *Ips* in *Thuringia*, whence it has its name, and is much of the nature of that sort of black slate which we have common in England, lying over the coal strata.

As our slate of this kind contains usually leaves of fern and other plants, this species kind contains the impressions of several kinds of fish, so exactly delineated in shape, and with the fins, scales, and all other parts so perfect, that the species are easily known. All these impressions and delineations are, however, so flat and thin, and have taken up so little room in the stone, that they seem rather to have been the ribs and exuvie of fish than the whole bodies of them; but this is not wonderful when we consider how exilic the bodies, and even the bones of fishes, may be dissolved; and that these exuvie are lodged in a substance which contains a vitriolic salt, very capable of effecting such a solution. It is easy to conceive, that this and other such salts, while in a state of solution in water, before the concretion of the matter of this stone into a hard mass, might make that water a medium capable of thus dissolving

ISABELLA, in *Conchyliology*, the name given by the French naturalists to the beautiful pale-brown voluta, so much esteemed in the Dutch cabinets.

ISAGON, in *Geometry*, is sometimes used for a figure consisting of several angles.

ISAIAH, or the *Prophet of IERUSALEM*, a canonical book of the Old Testament. *Isaiah* is the first of the four greater prophets; the other three being Jeremiah, Ezekiel, and Daniel. This prophet was of royal blood; his father Amos being brother to Azzur, king of Judah. The five first chapters of his prophecy relate to the reign of Uzziah, the vision in the sixth chapter happened in the time of Jotham; the next chapters, to the captivity, include his prophecies under the reign of Ahaz; and those that were made under the reigns of Hezekiah and Manasseh, are related in the next chapters to the end. *Isaiah* foretold the deliverance of the Jews from their captivity in Babylon by Cyrus, one hundred years before it came to pass. But the most remarkable of his predictions are those concerning the Messiah, which describe not only his descent but all the remarkable circumstances of his life and death. The style of this prophet is noble, nervous, sublime, and fluid, which he acquired by converse with men of the greatest abilities and education; Grotius calls him the Demosthenes of the Hebrews. However the profoundness of his thoughts, the sublimity of his expressions, and the extent of his prophecy, render him one of the most difficult of all the prophets; and the commentators that have been hitherto written on his prophecy fall short of a full explication of it. Bishop Lowth's new translation, &c. published in 1758, throws considerable light on the composition and meaning of *Isaiah*.

ISAMBLUCUS, in *Natural History*, the name of a genus of fossils of the class of the *Stellata*, but of the columnar, not the rhomboidal kind. See *Tab. of Fossils, Class 2*. The striae of this genus consist of six sides, and two obtuse or almost ends; and all their sides being very nearly of the same breadth, they much resemble broken pieces of the columns of *Strophomena*.

The bodies of this genus, as well as the rest of the columnar striae, are subject to a longitudinal crack, which sometimes admitting a small quantity of clay, shapes it into the figure of an ear of grain. Hill's *Hill. of Fossils* p. 231. See the article *SELENITE*.

ISARUS, in *Zoology*, a name given by the ancients to the *Chamaeleon* goat.

ISATIS, in *Botany*. See *WEAN*.

ISATIS, in *Zoology*. See *LAGOPUS*.

ISATODES, a word used by Hippocrates, and some other of the old writers, to express a greenish colour of the bile discovered in the stools, which resembles the colour of the herb *Isatis*, or wood. This was esteemed an indication of a highly degenerated bile.

ISCHEMON, in *Botany*, a name used by many authors for the graft called *grana mance*, *manus gals*, or *Ruffa*-ferd.

ISCHNOPHONIA was also a word used by the ancients to express any thing given as a remedy in hemorrhages, or other fluxes of blood, whether from wounds or otherwise.

ISCHLENUM, in *Botany*, the name by which Linnæus calls the *fernaceous*, or carnal's hay. This makes a peculiar genus of plants of the *polygona minor* class; the characters of which are these: It has male and hermaphrodite flowers, distinct from one another; the male flower is very small, and always stands upon the glume of the cup of the female flower; its cup is a bivalve glume, with no awn, and containing only one flower; the flower is another bivalve glume of the size of the cup, and without awn; the stamens are three short capillary filaments, and the anthers simple; the hermaphrodite flower is larger; its cup is a large bivalve glume, placed within the common glume, and terminated by a twisted awn, or beard between each valve; the flower is a small double glume; the pistil consists of an oblong germin, and two reflex styles; all the glumes of the cup, flower, &c. continue to surround and inclose the seed; and they never drop it out till forced from them, each containing one seed.

ISCHAS, in *Botany*, a name given by Clusius, and some others, to those species of *rhytidum* or *serotum*, which have tubercles or knobby roots, and are called by others *opifera*.

ISCHENIA, *Ischia*, in *Antiquity*, anniversary sports celebrated at Olympia, in memory of Iphigenia, the grandson of Mercury and Hercules, who, in a time of famine, devoted himself to be a sacrifice for his country, and was honored with a monument near the Olympian stadium.

ISCHADIC, *Ischadicæ*, derived from *ischos*, or *ischos*, *ista*, the hip, in epithet given by physicians to two veins of the foot, which terminate in the crural.

The first, called the *great ischadic*, is formed by ten fine branches, proceeding from the toes, which, uniting together, pass by the muscles of the calf of the leg.

The lesser *ischadic* is formed by several ramifications, proceeding from the skin and muscles, which encompass the articulation of the thigh.—They are also called *ischiotomæ*.

ISCHIAS, *ISCHIADICA* or *ISCHIATICA*. See *SCIATICA*.

ISCHIO-CAVERNEXUS, in *Anatomy*, a name given by Winslow, and others of the *Vegetal* anatomists, to a muscle of the penis, called also by some the *posterior* and *external* penis, but now generally named, from its office, the *rector*.

ISCHIO-CAVERNEXUS is also applied by the same authors to a muscle of the female pudenda, called by some the *posterior clitoridis*, and *externalis manifestus masculis*, and by Cowper and Albinus, from its office, the *rector clitoridis*.

ISCHIUM, or *ISCHION*, derived from *ischos*, *robore*, *strength*, in *Anatomy*, the name of one of the bones of the hip; called also *os coxae* and *ischioides*.

In the *ischium* is a deep cavity, called *cavitas* or *acetabulum*, which receives the head of the thigh bone. This cavity is encompassed with a cartilaginous circle, which serves to strengthen the thigh.

The *ischium* is one of the *ossa innominata* of authors.—See *Tab. Anat. (Ossis)* fig. 3. lit. S. n. 19. fig. 12. lit. c. This is the lowest portion of the *os innominatum*, as also of the whole trunk. It is divided into the body, the tuberosity, and the ramus or branch.

The body of the *ischium* forms the lowest and greatest part of the acetabulum, and sends out an apophysis backward, called the spine of the *ischium*. The tuberosity is very thick, unequal, and turned downward; and it is on this part that the whole body rests when we sit. It appears cartilaginous, because of the dried and hardened remains of the tendons. The whole convex portion of it is originally an apophysis, of which the marks are obliterated sooner in some subjects than in others; three unconfused impressions may be distinguished in it.

The branch of the *ischium* is a kind of thin flat production, or apophysis, which ascends forward from the tuberosity of the curvature of the os pubis, and it is often covered in part by a continuation of the epiphyses of the tuberosity.

These three parts of the *ischium* taken together, form a large opening, which makes the greatest part of the foramen orale. Three other openings are remarkable in this bone: one posterior, between the tuberosity and the spine, for the passage of the internal obturator muscle, which is a little cartilaginous, and divided into three or four superficial channels; one lateral, between the tuberosity and the acetabulum, for the passage of the external obturator muscle; and one anterior, at the edge of the acetabulum for ligaments. Winslow.

ISCHNAMBLUCUS, in *Natural History*, the name of a genus of fossils of the class of the *SELENITE*, but one of those which are of a columnar form, not of the common rhomboidal one. See *Tab. of Fossils, Class 2*.

The word is derived from the Greek, *ischos*, *robore*, *strength*, *istis* or *istis*, and *ambly*, *obscure*, and expresses a body in form of a thin or flattened column, with obtuse ends. The bodies of this genus are of an octobulbar figure, consisting of six long planes and about two broken ends. The top and base planes are broader than the rest. The crack which runs through the whole length of bodies of this genus is often filled with clay, which spicula itself into the form of an ear of corn; grains of this genus there are only four known species. Hill.

ISCHNOPHONIA, formed of *ischos*, *robore*, *strength*, and *phonia*, *voice*, a word used by some authors to express that weakness and faintness of the voice which attends persons in some distempers; more usually, however, it is understood to express a stammering or imperfection in the speech.

ISCHURIA, *ischuria*, formed from *ischos*, *istis*, and *urine*, in *Physic*, a distemp consisting in an entire suppression of urine.

It is occasioned by any thing which may obstruct the passages of the *seminis*, *ureters*, or the neck of the bladder, as sand, stone, mucus, &c.—It may also arise from an obliquity of the nerves, which pass to the reins or bladder, as we see it does, in a palsy of the parts below the diaphragm.—The too great distention of the bladder may also produce the same effect; for the fibres being much lengthened, and consequently condensed, the spiritus necessary for their contraction cannot get admittance; whence it is that persons, who have retained their urine a long time, find a great deal of difficulty in discharging it. See *SUPPRESSION of urine*.

ISCUSTOS, a word used by the writers of the middle ages as the name of a gem, but seeming to be only a corrupt way of spelling albescent. Albertus says it was of a yellowish colour, and found in Spain, and that its fibrous texture made it capable of being wrought into cloth, which when thrown into the fire, was not consumed, but only cleaned by burning. See *ANASTOS*.

ISELASTICS, *Istloflia*, kind of games, or combats, celebrated in the cities of Greece and Asia, in the time of the Roman emperors.

The victors at these games had very considerable privileges conferred on them; after the example of Augustus, and the Athenians, who did the like to the conquerors at the Olympic, Pythian, and Isthmian games. They were crowned on the spot, immediately after their victory; had pensions allowed them; were furnished with provisions at the public cost; were carried home in triumph, and made to enter their cities through a breach in the walls; whence their appellation, from *exuvians*, is given.

ISIA, *Istia*, feasts and sacrifices annually solemnized in honour of the goddess Isis.

The *Istia* were full of the most abominable impieties; and for that reason, those who were initiated into them were obliged to take an oath of secrecy. They held for nine days successively, but grew so scandalous, that the senate abolished them at Rome, under the consulate of Piso and Gabinius. They were re-established by Augustus, and the emperor Commodus himself assisted at them, appearing among the priests of that goddess with his head shaven, and carrying the Anubis.

ISIAC TABLE is one of the most considerable monuments of antiquity, discovered at Rome in 1722, and supposed by the various figures in it to represent the fests of Isis, and other Egyptian deities. There have been various opinions as to the antiquity of this monument; some have supposed that it was engraved long before the time when the Egyptians worshipped the figures of men and women. Others, among whom is bishop Warburton, apprehend, that it was made at Rome, by persons attached to the worship of Isis. Dr. Warburton considers it as one of the most modern of the Egyptian monuments, on account of the great mixture of hieroglyphic characters which it bears.

ISIACI, priests of the goddess Isis.—*Isidorus* tells us, that they bore a branch of sea-wormwood in their hands instead of olive. They sang the praises of the goddess twice a day, viz. at the rising of the sun, when they opened her temple, after which they begged alms the rest of the day, and returning at night, repeated their orisons, and shut up the temple.

Such was the life and office of the *Isiaci*; they never covered their feet with any thing but the thin bark of the plant papyrus, which occasioned Prudentius and others to say they went bare-footed. They wore no garments but linen, because Isis was the first who taught mankind the culture of this commodity. See *Diogenes Siculus*, and *Plutarch's Isis and Osiris*.

ISINGLASS, a name given to Mulcory tale, and to *ferro-vicollai*; which see.

A strong glue is made of *isinglass* dissolved in spirit of wine. See *GLUE* and *LEUTHYCOLLA*.

ISINGLASS-FISH, the English name of the fish from which the drug called *isipaglia* or *isinglass* is made. It is a species of the *antipiper* or *sturgeon*, and is distinguished by not having any of the tubercles which the body of the common sturgeon has. See *ACCIPITER* and *HISIO*.

ISIR, or *IXIR*, a name used by some of the chemical writers for an elixir.

ISIS, in *Mythology*, a goddess of the ancient Egyptians, worshipped by them and many other nations; *Isis* is reported by *Diogenes Siculus* to have invented many excellent medicines; and hence, says he, after she was received among the number of the deities, she was applied to for the cure of distempers; and frequently indicated remedies by dreams. *Galen* takes notice of some phlegm which bear her name.

ISIS, in *Natural History*, a term used by *Linnaeus* to express a genus of *ZOOHYTES*, comprehending six different species.

ISKA, a name given by the ancients to a light kind of agaric, growing to the old stumps of the oak, hazel, and other trees. This being a very light kind of fuel, was used by the ancients in the manner of a cautery, as we have learned from the Indians in use moss or the down of mugwort leaves.

ISLAM, See *MAHOMETANISM*.

ISLAND, or *ISLE*, a tract of dry land encompassed with water; either with the sea, a river or lake. In which sense *island* stands contradiistinguished from *residence*, or *terra firma*.

Some conclude, that *islands* are as ancient as the world, and it is by no means probable, that the large *islands*, far remote from the continent, are new, or that they either arose out of the sea, or were torn from the main land. Nor is it less certain, that there have been new *islands* formed by the calling up of vast heaps of clay, mud, sand, &c. as that, for instance, of *Kiangning*, in the province of *Nankin* in China; or by the violence of the sea, which has torn off large promontories from

the continent, as the ancients imagined Sicily, and even Great Britain to have been formed. It is also certain, that some have emerged above the waves, as *Santorini* formerly, and three other *islands* near it lately, the last in 1707, which rose from the bottom of the sea, after an earthquake, that was supposed to have loosened it from its hold.

Several naturalists are of opinion, that *islands* were formed at the deluge; others think they have been rent and separated from the continent by violent storms, inundations, and earthquakes. Their labors have observed that the East-Indies, which abound in *islands* more than any other part of the world, are likewise more annoyed with earthquakes, tempests, lightning, volcanos, &c. than any other part.

Varenus thinks most of these opinions true in some instances, and believes that there have been *islands* produced each of these ways. St. Helena, *Atkinson*, and other steep rocky *islands*, he supposes to have become so, by the sea's overflowing their neighbouring champaigns. By the heaping up huge quantities of sand, and other terrestrial matters, he thinks the *islands* of Zealand, Japan, &c. were formed; *Sumatra* and *Ceylon*, and most of the East-Indian *islands*, he rather thinks were rent off from the main land; and concludes, that the *islands* of the Archipelago were formed in the same way; imagining it probable, that *Deucalion's* flood might contribute towards it.

The ancients had a notion, that *Delos*, and some few other *islands* rose from the bottom of the sea; which, how fabulous soever it might appear, agrees very well with some later observations. *Seneca* takes notice, that the *island* *Therapsia* rose out of the *Aegæan* sea in his time, of which the mariners were eye-witnesses.

ISLAND-ISLANDS. *Histories* are full of accounts of *floating-islands*, but the greater part of them are either false, or founded on exaggerations. What we generally see of this kind is no more than the concretion of the lighter and more viscous matter floating on the surface of water in lakes, and with the roots of plants, forming conglomerates of different sorts, which not being fixed to the shore in any part, are blown about by the winds, and float on the surface. These are generally found in lakes, where they are contained from being carried too far, and from being broken by the agitation of the water. And in process of time some of them acquire a very considerable size. *Seneca* tells us of many of these *floating-islands* in Italy; and some later writers have described not a few of them in other places. But however true the histories of these might have been at the time when they were wrote, there remain very few proofs of their truth at this time, these *islands* having either disappeared again, or been fixed to the sides, in some part, in such a manner as to have made a part of the shore. *Pliny* tells us of a great *island* which at one time floated about in the lake *Canalis*, in the country of *Retinam*, which was discovered to the old Romans by an oracle; and *Pomponius* tells us, that in *Lydia* there were several *islands* to loose in their foundations, that every little accident shook and removed them. *Herodotus* speaks also very largely of the lake *Chemalis* in Egypt. See *ASPORTATIONS of the Earth*.

Gryphander has written a Latin treatise expressly on *islands*, *de insulis*.

ISLANDS, *Fortunate*. See *FORTUNATE*.

ISLAND, *Crystal*. See *CRYSTAL*.

ISLAND-FISH, in the *Fish-trade*, a name given to the common *COD-FISH* when it has been caught and preserved in *brandy*.

ISLEBEIANUS *lepis*, in *Natural History*, a name given by authors to a kind of blackish fish, very heavy, not very hard, and easily splitting into thin flakes. It is dug near *Ipsa* in *Thuringia*, whence it has its name, and is much of the nature of that sort of black slate which we have common in England, lying over the coal strata.

As our slate of this kind contains usually leaves of fern and other plants, this foreign kind contains the impressions of several kinds of fish, so exactly delineated in shape, and with the fins, scales, and all other parts to perfect, that the species are easily known. All these impressions and delineations are, however, so flat and thin, and have taken up so little room in the stone, that they seem rather to have been the skins and exuviae of fish than the whole bodies of them; but this is not wonderful when we consider how easily the bodies, and even the bones of fishes, may be dissolved; and that these exuviae are lodged in a substance which contains a vitriolic salt, very capable of effecting such a solution. It is easy to conceive, that this and other such salts, while in a state of solution in water, before the concretion of the matter of this stone into a hard mass, might make that water a medium capable of thus dissolving

the bodies and bones of fishes, while the outer skin and scales being much tougher, and of a very different nature, might escape the effects of them. It is well known that the fins and scales, and other external parts of fish, are much more capable of bearing maceration in water than the internal substances of them; and it is easy to conceive that these, after having withstood that power in the water, would at length subside down among the middle matter that was in form some of the fins of this fish, the motion of the water would not fail to expand these fins, though ever so thin, into the flat and exact shape of the whole fish; and when thus laid along upon the surface of the new formed firmness, the exact quantity of the same matter that subsided would form another firmness, which filling evenly upon the former, would cover it, and on the following contraction of both, the figure of the fish would be beautifully preserved between two plates or flakes of a flexible stone.

It is very remarkable, that as in these fishes of fish preserving fishes, the external parts only are preserved, the bones and flesh being wasted; so, on the other hand, in those fishes brought from Syria, the skins and scales are wanting, and the skeletons are principally the part preserved. In some of these the bones are not clean, small parcels of the flesh being found petrified among them; but this flesh is stripped of the skin. The stone in which these Syrian fishes are preserved is also very different from the lith stone, being whitish or greyish, and very hard. The stones of this kind found on mount Libanus, where they are very common, have very fine delineations of the star-fish complete. Woodw. Cat. Foss. vol. ii. p. 23, 30.

ISLEBIANS, in Ecclesiastical History, a name given to those who adopted the sentiments of a Lutheran divine of Saxony, called John Agricola, a disciple and companion of Luther, a native of *Isle*, whence the name; who, imitating literally some of the precepts of St. Paul with regard to the Jewish Law, declaimed against the law and the necessity of good works. See ANTIOMIANS.

ISLES, in Architecture, the form or wings of a building.

ISNARDIA, in the Linnæan system of Botany, the name of a genus of plants, of the *Isnardia monogyna* class; the distinguishing characters of which are these: the cup is a perianthium, formed like a bell, slightly divided at the extremity into four pointed segments; it has no petals; the stamens are four filaments, growing out of the middle of the cup; the anthers are simple; the germ of the pistil is inclosed in the substance of the cup; the style is simple, and longer than the stamens; and the stigma is thick and large; the fruit is made out of the base of the cup, which is square, and has four cells; the seeds are few in number, and of an oblong figure.

ISOCRONAL, or **ISOCRONOUS**, is applied to such vibrations of a pendulum, as are performed in equal times.

Of which kind are all the vibrations or swings of the same pendulum, whether the arc it describes be longer or shorter; for when it describes a shorter arc, it moves so much the slower; and when a long one, proportionally faster.

ISOCRONAL LINE, is that wherein a heavy body is supposed to descend without any acceleration.

Leibnitz, in the *Act. Erud. Lips.* for April, 1689, has a discourse on the *Linea isochrona*, in which he shews, that a heavy body, with a degree of velocity acquired by its descent from any height, may descend from the same point by an infinite number of *isochronal* curves, which are all of the same species, differing from one another only in the magnitude of their parameters; such as are all the quadratic paraboloids, and consequently similar to one another. He shews also, how to find a line, in which a heavy body descending, shall recede uniformly from a given point, or approach uniformly to it. See CYCLOID.

ISOETES, in Botany, a genus of the *cryptogamia* class of ferns; the characters of which are, that the small flowers form an anthera, within the base of the leaf, and the female a double-celled capsule in the same situation.

ISOMERIA, formed of *isos*, equal, and *meros*, part, in Algebra, a method of finding an equation from fractions, by reducing all the fractions to one common denominator, and then multiplying each member of the equation by that common denominator.

This assumes to the same with what is otherwise called conversion of equations.

ISOPERIMETRICAL Figures, are such as have equal perimeters, or circumferences.

It is demonstrated in geometry, that among *isoperimetric* figures, that is always the greatest which contains the most sides or angles.—From whence it follows, that the circle is the most capacious of all figures, which have the same circumference with it.

That of two *isoperimetric* triangles, which have the same base, and one of them two sides equal, and the other unequal; that is the greater whose sides are equal. That of *isoperimetric* figures, whose sides are equal in number, that is the greatest which is equilateral, and equiangular.

Hence flows the solution of that popular problem, To make the hedging or walling, which will fence in one acre, or any other determinate number of acres, &c. hence in any other greater number of acres whatever, &c. For, call x one side of a parallelogram, whose area is the number of acres a ; then will $\frac{a}{x}$ be the other side, and $2x + \frac{a}{x}$ will be the perimeter of the parallelogram, which must be equal to four times the square root of a , that is, $2x + \frac{a}{x} = 4\sqrt{a}$, whence the value of x will easily be

had by the solution of a quadratic equation; and infinite numbers of squares and parallelograms may be made, which shall have the same perimeter, yet different areas.

E. g. if one side of a square be 15, and one side of a parallelogram be 19, and the other 1, such square and parallelogram will be *isoperimetric*, viz. each 40; yet the area of the square will be 100, and of the parallelogram only 19.

Isoperimetric lines and figures have greatly engaged the attention of mathematicians since the invention of fluxions; that, among all those of the same perimeter produce maxima and minima, was given by Mr. James Bernoulli, from considerations that involve second and third fluxions. And several questions of this nature have been since prosecuted in like manner, but not always with equal success. Mr. Mac Laurin, to vindicate the doctrine of fluxions from the imputation of uncertainty, or obscurity, has illustrated this subject, which is commonly considered as one of the most abstruse parts of this doctrine, by giving the resolution and composition of these problems by first fluxions only, and in a manner that suggests a synthetic demonstration, tending to verify the solution. *Analys. inquit Problemata isoperimetrica*, Act. Erud. Lips. 1701. p. 214, seq. See Mac Laurin's Fluxions, book i. chap. 13. p. 420, seq. See also Mem. Acad. Science, 1726, 1718, and Jo. Bernoulli Opera, tom. i. p. 207, 208, 424, seq. tom. ii. p. 235, 604.

ISOSEPHUS, in Jurisprudence, an appellation given to judges, who had equal jurisdiction and authority; it was likewise applied to a case where the votes were equal on both sides. Another sense is given to it, viz. when the letters of different words make up the same tone, they were said to be *isosephus*; for the Greeks had no other cyphers to number with, but the letters of their alphabet; so that a signified one, β two, γ three, &c. But beside words, the accents had likewise various uses of this kind; and it is pretended that there are several such verses in Homer. Hist. Acad. Inscrip. vol. iii. p. 311, seq.

ISOSEPHUM, in Botany, a genus of the *pentandria polygyna* class. Its characters are these: the flower has no corolla; but has five oval petals, and five short tubulous nectaries, situated within the petals; it has a great number of short hairy stamens, and several oval germs, which afterwards become so many rounded capsules, with one cell, filled with small seeds. There are three species.

ISORA, in Botany, the name given by Pline to a genus of plants, called by Linnaeus, *HELIOTRIS*.

ISOSCELES triangle, is one, equal, and *isos*, like, is a triangle which has two equal sides. In an *isosceles* triangle, FDE (Tab. III. Geometry, fig. 57.) the angles Y and z , opposite to the equal sides, are equal; and a line drawn from the top or vertex, F, cutting the base into two equal parts, is perpendicular to the base. The same line also bisects the vertical angle of the triangle. It appears likewise, that if the equal sides be produced, the angles under the base will be equal, the sum of those above and below respectively being equal to two right angles. And if the vertical angles of two *isosceles* triangles be equal, the two triangles will be equiangular. Moreover, every equilateral triangle must be equiangular. See KITE-FISH.

ISSONGI, in Botany, a name given by the people of Guinea to a species of plum, which they infuse in water, and afterwards boil, and then wash the head with it, as a cure for all kinds of the head-ache. It is a plant described by the botanical writers under the name of *pitum vesicarium* *Fruta nigra, alba macula nuda*, the bladder-pear, with a black fruit marked with a white spot; and called by the people of Malabar, where it also grows very plentifully, *ungwa*. It is also found in Barbadoes and Jamaica, and is there called *parley*. Philoz. Trans. N° 232.

ISSUANT, in Heraldry, is understood of a lion, or other animal, in a coat of arms, that seems just coming

quently fall off. There issues from the scabs white sanguineous matter, and the whole texture of the skin is altered; the cuticle being beset with small scales, and feeling rough like the skin of an elephant, whence the disease has been called by some *elephantiasis*.

In other respects, this complaint is attended with no sensation of pain, or uneasiness; but the face is inflamed, the teeth become black, the breath becomes foetid, and tumour of the bubo kind appear on several parts of the body, all which become finally malignant ulcers; and in the progress of the disease, large scabs, with portions of the skin, fall from different parts of the face.

Persons subject to the itch. These are principally men of a sanguineous temperament of body and phlegmatic disposition, who most easily fall into the moist *itch* of the simple and benign kind, and are of all others most difficultly cured of it. Those, on the other hand, who are most subject to the simple dry *itch*, are men of a dry temperament and choleric habit. All persons who eat coarse foods, with much salt, and drink sour and decayed liquors, easily fall into this kind; as also such as live in a damp foggy air, and those who are subject to obstructions of the liver, and who have long been afflicted with quartans. Those who have a suppression or diminution of the usual quantity of urine, and by that means have the fat ferocities of the blood not duly carried off, are also more subject than others; as also, from the same cause, are such as have had old ulcers suddenly stopped, or issues dried up; people who have been used to cupping, at certain regular times, and afterwards neglect it; and finally, those of an idle and sedentary course of life.

Cause of it. The causes of the simple benign *itch* are a stasis and corruption of the lymphatic humours, and this is often occasioned by the humid temperament of the air, which in cold seasons prevents the going off of those humours by sweat, which had been directed to the skin by nature for that purpose, hence they remain there and corrupt; and there are other things which more or less concur to causing it; there are a change of the food and drink continued for some time, and with this a plethoric habit of body. It is sometimes the crisis of other diseases, as of a quartan, &c. These are the causes, and these the persons subject to the *itch*, as a primary disease beginning with them; but its usual method of propagating itself is by contagion; filthy people, at least, having it by this means, for one, on whom it appears of itself. A free use of salted food greatly exacerbates the *itch* in all persons, but this alone can have but little effect towards the original producing it. The malignant or complicated *itch* owes its origin to other causes. The ferine *itch* is always caused by the scurvy, and the venereal or pocky *itch* owes its origin to the corruption of the lymph in the venereal disease.

Dr. Bonomo has given another account of the cause of this distemper, which is adopted by Dr. Mead: he carefully examined several globules of the matter picked out of the pustules of itch persons with a microscope, and found them to be minute living creatures, in shape resembling a tortoise, of brittle motion, with six feet, a sharp head, and two little horns at the end of the snout.—Hence he makes no scruple to impute this contagious disease to the continual biting of these animalcules in the skin; by means of which some portion of the serum oozing out through the small apertures of the cutis, little watery bladders are made, within which the insect continuing to gnaw, the infected are forced to scratch, and by scratching increase the mischief; breaking not only the little pustules, but the skin too, and some little blood-vessels, and so making feabs, crusty sores, &c. But it has been supposed by others to be more probable, that the small insects or *acari*, which are often found in the pustules of the *itch*, make choice of these as a proper nidus, and do not originally occasion them. See *ANIMALCULES*. Hence we perceive how the *itch* comes to be catching; since these creatures, by simple contact, may very easily pass from one body to another; their motion being wonderfully swift, and they crawling on the surface of the body, as well as under the cuticle.

Hence also we learn the reason of the cure of this disease by lustral washes, baths, and ointments made of salts, sulphur, mercury, &c. these being very powerful in killing the vermin lodged in the cavities of the skin, which scratching will never do, they being too minute to be caught under the nails. And if in practice it is found, that this disease, after it seemed to be cured by unction, frequently returns again, this is easily accounted for; hence, though the ointment may have killed all the living creatures, yet it may not, possibly, have destroyed all their eggs laid, as it were, in the nests of the skin; from which they afterwards breed again, and renew the distemper.

ITCH, prophetic in the. The simple benign *itch*, of the moist kind, is the mildest of all the kinds, and in general the most

easily cured; but as it is more subject to ulcerations than the other kinds, this sometimes makes the cure in bad habits of body more difficult. The dry *itch* is more troublesome, and takes more time in the cure than the moist, and is more troublesome to the patient; but in the moist, famous, and suppurating *itch*, when it is rashly treated by mercurial and sulphureous ointment, by quicksilver girdles, by astringents and refrigerants, and is driven in, which is a very common case, there always arise very unhappy symptoms, such as anxieties of the præcordia, affluens, suffocative catarrhs, intermittent fevers, and sometimes inflammatory acute ones, both which are of a different appearance from those distempers in their usual state; not unfrequently also terrible chronic complaints are brought on by this, as cachexies, anasarca and oedemas. The *itch*, in general, when newly caught by infection, is always much more easily cured than when it arises from a fault in the humours, and is consequently much more deeply rooted; for the same reason, the chronic *itch* is of all others the most difficult to be cured; and where there concurs with it a defect or fault of some of the viscera, as is too often the case, the cure is yet greatly the more difficult. The malignant *itch* is always much more deeply rooted in the patient, and of consequence is much more difficult of cure than the simple; and in particular, the ferine or scorbatic *itch* is one of the most stubborn diseases we know of. In this case the food, and other circumstances, often make the cure much more difficult than it naturally would be: poor people are often infected with this; and their diet not being in their choice, are with difficulty cured of it. The venereal *itch*, though generally accounted the most terrible of all the kinds, is yet much more easily cured than the scorbatic, and sometimes than the simple chronic kind, when treated in a proper manner.

Method of cure. The corrupt state of the humours is to be corrected according to the several kinds. In the benign *itch*, this is effected by alexipharmics and diuretics, such as decoctions of the woods of guaiacum, sassafras, and the like, with elecampane and pimpinell roots, and the common absorbents laced with acids, as the crab-eyes, or oyster-shells, saturated with lemon juice, or the like; and the acrimony of the humours is greatly taken off by sulphur and nitre given in powders, or by the simple balsam of sulphur in oil of almonds. After this, external applications complete the cure; of this kind are the mercurial ointments, and those which contain sulphur. But mercurial unctions cannot be depended upon for this effect, unless in light cases; as their antipruritic efficacy seems to reach no farther than those parts of the skin to which they are applied, and as they cannot with safety be applied freely, to any great extent of the body, particularly of the trunk. In the dry *itch* counteractions and baths do much more than ointments; and of this kind are decoctions of the oxylapachum root, and a litiavium of quick lime and sulphur, or the general bathing in mineral springs.

In the malignant *itch*, the ferine or scorbatic is to be treated as the scurvy, to which it owes its origin. The antiscorbatic juices should be taken for some time, and the decoction of tobacco made very strong, is a good external application; mercurial ointments have also their use here, and the violent heat of the eruptions may be mitigated by camphor, and by the frogs spawn plaster.

In the venereal *itch*, the method to be used for a cure is the same with that for the venereal disease in any other appearance; but in this there must be always kept up a gentle perspiration: mercurial ointments have peculiarly a place here; and when the disease is so rooted as to give way to no other means, recourse is to be had to a salivation; and finally, the cure is to be completed by evacuating the corrupted humours by stool, in which case calomel is a very useful ingredient in purges, and the decoctions of the diaphoretic and diuretic vegetables are of great service in completing it, and preventing a return. *Junker Consil. Med. p. 452, &c.*

The best medicine yet known for the *itch* is sulphur, which should be used both externally and internally. The parts most affected may be rubbed with an ointment made of the flowers of sulphur two ounces, crude sal ammoniac finely powdered, two drams; hog's lard, or butter, four ounces; to which may be added a scruple, or half a dram of the essence of lemon, in order to take away the disagreeable smell. About the quantity of a numism of this may be rubbed upon the extremities, at best time, twice or thrice a week. Before the patient begins to use the ointment; if he be of a full habit, he ought to be bled, or take a purge or two. During the use of it, he should also take, night and morning, as much of the flower of brimstone and cream of tartar, in a little treacle or new milk, as will keep the body gently open; and take care of catching cold. The quantity of ointment

above

above directed will generally suffice for the cure of one person; but if any symptoms of the disease remain, the medicine may be repeated. Mercury is a dangerous, and has often proved a hurtful medicine in this disease, and should be used with great caution. Mercurial girdles have produced many lamentable effects. Those who would avoid this disease ought to beware of infected persons, to use wholesome food, and study universal cleanliness. — *Fuchsian.*

LEUCÆMA, a creature said to be found in the pulsules of the *stellæ*; it is a species of *ACARUS*.

ITREA, in *Botany*, a name used, by the ancients in general, to signify the willow; but, by some of the Greek writers, it is also used as a name for the pine.

ITREA, in the *Linnean System of Botany*, is a genus of the *pentandra monogyna* class: the characters are, that the empanment of the flower is small, permanent, and erect, ending in five acute points; the flower has five petals, inserted in the empanment, and five awl-shaped stamens as long as the petals, terminated by roundish summits, and an oval germen supporting a cylindrical permanent style; the germen becomes a long oval capsule, with the style at the top, having one cell filled with small seeds. — *Miller.*

ITHYNERION, *thyrapsus*, in *Antiquity*, a staff of laurel, which prophets usually carried in their hands, otherwise called *thyrus*.

ITINERANT judges, or *judices*, such as were formerly sent with commissions into divers counties, to hear chiefly those causes called *pleas of the crown*: the same with what are otherwise called *justices in eyre*. — See **JUSTICE**.

ITINERARIUM, in *Surgery*, a name given by Hildanus, and many other writers, to a staff used in the operation of curing for the stone.

ITINERARY, the description a traveller gives of the course of his journey, and of the curiosities, &c. he observed therein.

The *Itinerary* of Antonine shews all the grand Roman roads in the empire, and all the stations of the Roman army. It was drawn up by order of the emperor Antoninus Pius; but it is now very defective, having suffered much under the hand of the copists and editors.

ITINERARY column. — See **COLUMN**.

ITERATION. — See **REITERATION**.

ITING, in *Natural History*, a name given by the people of the Philippine islands to a bird common among them, and resembling, by the description, to be of the woodpecker kind. It is of the biggest of the flaxing. It is a very noisy bird, but its voice is not disagreeable. People say this bird has but one strain gut.

IWA, in *Botany*, a genus of the *monocotyledon* class; the characters of which are, that the plants have male and female flowers; the male flowers have a common three-leaved empanment; the flowers that form the disc have one petal cut into five parts at the brim; the receptacle is distinguished by its hairs; the empanment of the female flowers is composed of five scutellous radii, which have no corolla; two long styles, and a naked oblong seed.

IVATAIL is the name of one of the canoes or boats used by the inhabitants of the Sandwiches, for short excursions to sea; it is wall-sided and flat bottomed. These boats are of different fizes, their length being from seventy-two feet to ten; but their breadth is by no means in proportion; for those of ten feet are about a foot wide, and those of more than seventy are scarcely two. The fighting *ivatail* is the longest, with its head and stern considerably raised above the body, in a semicircular form; the stern is sometimes seventeen or eighteen feet high. When they go to sea they are fastened together side by side, at the distance of about three feet, by strong poles of wood, laid across and lashed to the gun-wales. On these, in the fore-part, a stage or platform is raised, about ten or twelve feet long, somewhat wider than the boats, and supported by pillars about six feet high: on this stage are ranged the fighting men, whose missile weapons are darts and spears; and below the stage the rowers sit. The fighting *ivatail* are from forty feet long to ten; those of twenty feet and upwards occasionally carry sail. The travelling *ivatail* is always double, and furnished with a small neat house about five or six feet broad, and six or seven feet long. — *Hawkesworth's Voyages*, vol. ii. p. 221.

IVAPECANCA, in *Botany*, a name given by some authors to the climbing plant, of which the *fariparilla*, used in medicine, is the root.

JUBILEE, among the *Jews*, denotes every fiftieth year, being that following the revolution of seven weeks of years; at which time all the slaves were made free, and all lands required to their ancient owners. The *Jubiles* were not repeated after the Babylonian captivity.

The word, according to some authors, comes from the Hebrew, *jolel*, which signifies *fifty*; but this must be a

mistake, for the Hebrew *יובל*, *jolel*, does not signify *fifty*; neither do its letters, taken as cypher, signify according to their numerical power, make *fifty*; being 10, 6, 3, and 30, that is, 59. It is very probable, that *jolel* signifies a *year*, and that the word called *jubilee*, proclaimed with a trumpet, in remembrance of the ram that appeared to Abraham, is thickened. Mafius chooses to derive the word *jubilee* from the first inventor of musical instruments, whose name, or creation, were called by his name; whence *jolel* and *jubilee* came to signify the year of jubilee, and remission, because proclaimed with the sound of those instruments which at first was no more than of a ram. Others derive *jolel* from *יובל*, *jolel*, which signifies to recall, because this year restored all slaves to their liberty. The institution of this festival is in Lev. xxv. The learned are divided about the year of *jubilee*, maintaining that it was every forty-ninth, and others that it was every fiftieth year. The ground of the opinion is chiefly this, that the forty-ninth year is counted a sabbatical year, if the *jubilee* had been the fiftieth, the land must have had two fallow years without a sabbath, which, without a sabbath, would have produced a dearth. On the other hand, it is alleged, that the Scripture expressly declares for the fiftieth year, Lev. xxv. 10, 11. And besides, if *jubilee* and sabbatical year had been the same, there had been no need of a prohibition to sow, because this kind of labour was prohibited by the law of the sabbatical year. Lev. xxv. 4, 5. The authors of the Universal History, book ii. chap. 7, note R, endeavour to reconcile these opinions, by observing, that as the *jubilee* began in the first month of the civil year, which is the seventh of the ecclesiastical, it might be said to be either the forty-ninth or fiftieth, according as one or other of these computations were followed. The political sign of the law of the *jubilee* was to prevent the too oppressive of the poor, as well as their being in perpetual slavery. By this means a kind of equality was preserved through all the families of Israel, and the distinction of tribes was also preserved, that they might be able, when there was occasion, on the *jubilee*, to prove their right to the inheritance of their ancestors. It served also, like the Olympiads of the Greeks, and the Lustræ of the Romans, for the reader computation of time. The *jubilee* has also been supposed to be of the gospel state and dispensation, described by Ixi. ver. 1, 2, in reference to this period, as the "able year of the Lord."

JUBILEE, in a more modern sense, denotes a grand solemnity, or ceremony, celebrated at Rome, at which the pope grants a plenary indulgence to all sinners, at least to as many as visit the churches of St. Peter and St. Paul at Rome.

The *jubilee* was first established by Boniface VIII. in 1300, in favour of those who should go ad *sanctam urbem*; and it was only to return every hundred years. But the first celebration brought in such flow of pilgrims to Rome, that the Germans call this the golden jubilee, which occasioned Clement VI. in 1343, to reduce the period of the *jubilee* to fifty years. Urban VI. in 1389, appointed it to be held every thirty-five years, the age of our Saviour; and Paul II. and Sixtus IV. in 1475, brought it down to every twenty-five, the age of the person might have the benefit of it once in his life. Boniface IX. granted the privilege of holding *jubiles* to several princes, and monasteries; for instance, to the monks of Canterbury, who had a *jubilee* every fifty years, when people flocked from all parts to visit the tomb of Thomas a Becket. *Jubiles* are now become more frequent, and the pope grants them as often as the church, or himself, have occasion for them. There is usually one at the inauguration of a new pope.

To be intitled to the privileges of the *jubilee*, the bull joins fasting, alms, and prayers. It gives the priests a full power to absolve, in all cases, even those otherwise reserved to the pope: to make commutations of vows, &c. in which it differs from a *plenary indulgence*. During the time of *jubilee*, all other indulgences are suspended. One of our Kings, viz. Edward III. caused his birth-day to be observed in manner of a *jubilee*, when he became fifty years of age, in 1364, but never before or after. This he did, by releasing prisoners, pardoning all offences except treason, making good laws, and granting many privileges to the people.

There are particular *jubiles* in certain cities, when several of their feasts fall on the same day: at Fuentenay, for instance, when the feast of the Annunciation happens on Good-Friday; and at Lyons, when the feast of St. John Baptist concurs with the feast of Corpus Christi.

In 1640, the Jesuits celebrated a solemn *jubilee* at Rome; that being the centenary, or hundredth year from their institution,

coming out from under a chief, felle, a houle, a wood, or the like; and only shews half his body.

It is not very easy to distinguish the lion *issuant* from the lion rampant: some say the *issuant* is that which comes out from the bottom of the chief, shewing his head, neck, the tip of his fore-legs, and his tail, against the chief of the coat; whereas the rampant has its rife about the middle of the field, and shews all his fore-part, with the tip of his tail, as if he were rising out of the cirth.

ISSUE, in *Common Law*, has divers applications; being sometimes taken for the children begotten between a man and his wife—sometimes, for profits growing from amercements or fines—sometimes, for profits of lands and tenements—but more frequently, for the point of matter depending in fact, whereupon the parties join, and put their cause to the trial of the jury.

In all these occasions, *issue* has but one signification, which is, an effect of a cause preceding; as the children are the effect of the marriage between the parents; the profits growing to the king or lord, from the punishment of any man's offence, are the effect of his transgressions; the point referred to the trial of twelve men, is the effect of pleading, or process.

Issues concerning causes are of two kinds; that upon matter of fact, and that upon matter of law. An *issue* in fact is when the plaintiff and defendant have agreed upon a point to be tried by a jury; and *issue* in law is when there is a demurrer to a declaration, plea, &c. and a joinder in demurrer, which is an *issue* at law to be determined by the judges. *Issues* in fact are either general or special.

Issue, General, seems to be that whereby it is referred to the jury to bring in their verdict, whether or no the defendant hath done any such thing as the plaintiff lays to his charge.

For example, if it be an offence against any statute, and the defendant plead Not guilty, this being put to the jury, is called the *general issue*.—So if a man complains of a private wrong, which the defendant denies, and pleads no wrong, nor diffidence, and this be referred to the jury; it is likewise the *general issue*.

Issue, Special, is that, wherein special matters being alleged by the defendant in his defence, both parties join on this point, and so go to a demurrer, if it be *quæsitum juris*; or else to a trial by the jury, if it be *quæsitum facti*; as in assault and battery, where the defendant pleads that the plaintiff struck first.

Issue, Engaged, in *Chancery*, is used when a matter of fact is strongly controverted and the court directs the matter to be tried by a jury; but as no jury can be summoned to attend this court, the fact is usually directed to be tried at the bar of the court of king's bench, or at the assizes upon a *signed issue*. For, in order to bring it there, and have the point in dispute and that only put in *issue*, an action is feigned to be brought, wherein the pretended plaintiff declares, that he laid a wager of *xl.* with the defendant, that *A.* was heir at law to *B.* and then avers that he is *fo.* and brings his action for the *xl.* The defendant allows the wager, but avers that *A.* is not the heir to *B.*; and thereupon that *issue* is joined, which is directed out of chancery to be tried; and thus the verdict of the jurors at law determines the fact in the court of equity. These *signed issues* seem to be borrowed from the *spolia judicialia* of the Romans and are also frequently used in the courts of law, by consent of the parties, to determine some disputed right without the formality of pleading, and thereby to save much time and expence in the decision of a cause. Blackst. Com. book iii. p. 452.

Issues on Juris are for neglects and defaults, by amercement and fine to the king, levied out of the *issues* and profits of their lands; or double or treble *issues* may be laid on a herself for not returning writs, &c. But they must be taken off before they are entered into the exchequer, by rule of court, or good reason shewn. *Issues* shall be levied on jurors, for non-appearance; though on reasonable excuse proved by two witnesses, the justices may discharge the *issues*.

ISSUES, in *Physic and Surgery*, small artificial apertures in a fleshy part of the body, to drain off superfluous moisture, or give vent to any noxious humour. They are usually made in the arms, legs, or back, either by caustics or incision. Caution is used to place them about the middle of a muscle, that the necessary motion of the part may not incommode them, or pain the patient. There is an easy way of making an *issue*, which succeeds best in children; it is done after this manner: having applied a small piece of blistering plaster, about the bigness of a small pea, to the part where you would have an *issue*, and letting it lie on for a few hours, it will cause a blister; the skin being raised, apply a pea, as usual; and compress it tight with a bandage, till by degrees it sinks in, and forms an *issue*.

VOL. II. N^o 190.

The method by incision is performed thus: first mark the proper place with ink; then elevating the integuments between the thumb and fore-finger of the surgeon and an assistant on each side, you next proceed to make an incision through them, either with the scalpel or lancet, big enough to admit a pea, which being inserted and covered with a plaster and compress, nothing more than your roller is wanting to complete the operation. Thus by cleaning and dressing the wound every morning and evening with a fresh pea, it by degrees, in a day or two, degenerates into a little ulcer, discharging daily a quantity of purulent matter, which should be carefully cleaned or wiped off at every dressing.

There is a second method of making *issues* by wounding the skin with an actual cautery, or red-hot iron, which is usually included in a coat of capsula, or case of iron, to conceal it from terrifying the patient. When the case is fixed upon the proper part for the *issue*, the red-hot iron is then pressed down upon the integuments, and the eschar or burn is next to be dressed with fresh butter or basilicon, till by repeating the dressing every day, it separates, and then, the ulcer formed, it is to be filled with a pea, and dressed as before.

The third method of making *issues* is by the application of potential caustics, or corroding medicines; in order to which a piece of plaster is first perforated, and then applied, so as its aperture may cover the place marked with ink for the *issue*; a piece of the caustic is then put into the aperture of the plaster, and retained close down upon the skin, with some scraped lint, a small compress, and a large plaster; and lastly, with a larger compress and bandage. The patient is then to be ordered to rest for about six or eight hours, more or less, according to the strength of the caustic, which time being elapsed, and the dressings removed, the eschar is to be treated as before directed in an actual cautery.

In whichever of these methods the *issue* is made, it must be dressed at least twice every day, especially if it runs well, and in the summer season; and at each dressing you must put in a fresh pea, and cover it with a clean plaster, or a piece of waxed paper or silk, or an *ivy leaf*, retained with compress and bandage. But the indication for *issues* is much more commodiously performed with a leathern swathe, fastened by clasps, than by a circular linen roller. In this manner *issues* are to be kept open till the patient is recovered of the disorder for which they were made.

Issues are chiefly made for various disorders in the head, eyes, ears, teeth, scalds, and other painful disorders, which are this way frequently relieved or cured. But in Rabburn disorders it is frequently necessary to make two or more *issues* to produce any considerable effect, as one in each arm, or in one arm and leg of the same side. In this case proper topical remedies as camphairs, black hellebore, &c. should be speedily applied.

Issues above the shoulder-blades are good in asthmatic cases; and Dr. Mead thinks their benefit, in this and some other distempers, lies not only in giving vent to the humours, but likewise in lessening the over-great tension of the nerves. Monit. et Præcept. Medic. cap. v. The use of *issues*, or setons, made in the side on the part most affected, is recommended instead of bleeding, in consumptive cases. See CONSUMPTION.

In order to close an *issue*, little more is required than to discharge the pea, and to refrain from putting in any more, by which means alone it will close up in a short time; but if any proud flesh should arise, it may be amputated, or else removed with burnt alum. Lastly, it is observable, that when the *issues* of people far advanced in years cease to make their wonted discharge, and turn of a livid and blackish hue, it is a sign that they are invaded by some desperate disorder, and that life is very near its period.

IS THIMIA, *Idem*, or *ISTHMIAN Games*, *Lois Isthmiques*, were solemn sports, being one of the four sacred games celebrated in ancient Greece.

They were called *Isthmian*, because they were celebrated in the Corinthian Isthmus, a neck of land by which Peloponnesus is joined to the continent.

Plutarch, in the life of Theseus, tells us, they were instituted by that hero to the honour of Neptune; in imitation of Hercules, who had before instituted the Olympic games to the honour of Jupiter; but Archias refers their institution to the honour of Melicertes, or Palæmon, son of Althamus king of Thebes, whom the Latins call Porturnus. Others say, they were instituted by Nisus, son of Neptune; and others, by Sisyphus, brother of Althamus, king of Corinth, about 1350 years before Christ. Others are of opinion that there were two distinct solemnities observed in the Isthmus, one in honour of Melicertes, and another in honour of Neptune.

Archias and others say, the conqueror's prize at these games was a crown of parsley.—Plutarch and Strabo

lay, it was at first a crown of pine; and that this was afterwards changed for one of parsley; but that at length the pine was refused; and to this was added a reward of one hundred silver drachmæ.

These games were held, according to Pindar, every three years, or, according to Pliny, every five; and were esteemed so sacred, that after the destruction of Corinth, by Mummius, about 146 years before the Christian æra, the Sicynians were charged with the keeping them up. They were so celebrated, and the concourse at them was so great, that only the prime persons of the most remarkable cities could have place in them.—The Athenians had only as much room allotted them as the fall of a ship, which they sent yearly to Deles, could cover.

ISTHMUS, *isthmus*, in *Geography*, a narrow neck, or slip of ground, which joins two continents; or joins a peninsula to the terra firma, and separates two seas. The most celebrated *isthmuses* are that of Panama or Darien, which joins North and South America; that of Suez, which connects Asia and Africa; that of Corinth, or Peloponnesus, in the Morea; that of Crim-Tartary, otherwise called Taurica Cheronesos; that of the peninsula Romania and Ensis, or the *isthmus* of the Thracian Cheronesos, twelve furlongs broad; being that which Xerxes undertook to cut through. The ancients had several designs of cutting the *isthmus* of Corinth, which is a rocky hillcock, about ten miles over; but they were all vain, the invention of sluices being not then known.—There have been attempts, too, for cutting the *isthmus* of Suez, to make a communication between the Red Sea and the Mediterranean.

ISTHMUS is also applied by the anatomists to several parts of the human body, particularly that narrow part of the throat, situate betwixt the two tonsils.

Also to the ridge that separates the two nostrils; and to the passage in that part of the medulla oblongata of the brain, which lies between the cerebrum and cerebellum, and which reaches from the place called *pons* to the fourth ventricle. The upper part or cover of this conduit, or passage, which is betwixt the testes and the foremost vermicular process of the cerebellum, and to which two it is tied at its two ends, and to the processes which come from the cerebellum to the testes at its sides, is called *valvula major*; it is of a medullary substance, and its use is to keep the lymph from falling out above the nerves in the basis of the skull.

ITAIARA, in *Ichthyology*, a name by which some have called a Brazilian fish, of the turdus kind, of great beauty, and a very delicate taste, more usually known by the name *JURUNCAPEBA*.

ITALIAN, the language spoken in Italy.

This tongue is derived principally from the Latin, and of all the languages formed from the Latin, there is none which carries with it more visible marks of its original than the *Italian*.

It is accounted one of the most perfect among the modern tongues. It is complained, indeed, that it has too many diminutives and superlatives, or rather augmentatives; but without any great reason; for if those words convey nothing farther to the mind than the just idea of things, they are no more faulty than our *piccolinos* and *hyperboles*.

The language corresponds to the genius of the people; they are slow and thoughtful; and accordingly, their language runs heavily, though smoothly; and many of their words are lengthened out to a great degree.—They have a great taste for music; and, to gratify their passion this way, have altered abundance of their primitive words; leaving out consonants, taking in vowels, softening and lengthening out their terminations, for the sake of the cadence.

Hence the language is rendered extremely musical, and succeeds better than any other in operas, and some parts of poetry; but it fails in strength and nervousness; hence also a great part of its words, borrowed from the Latin, become so far disguised, that they are not easily known again.

The multitude of foreign names into which Italy is divided, has given rise to a great number of different dialects in that language; which, however, are all good in the place where they are used.—The Tuscan is usually preferred to the other dialects, and the Roman pronunciation to that of the other cities; whence the *Italian* proverb, *Lingua Toscana in bocca Romana*.

The *Italian* is generally pretty well understood throughout Europe, and is frequently spoken in Germany, Poland, and Hungary.—At Constantinople, in Greece, and in the ports of the Levant, the *Italian* is used as commonly as the language of the country; indeed in those places it is not spoken so pure as in Tuscany, but is corrupted with many of the proper words and idioms of the place; whence it takes a new name, and is called *Frank Italian*. See *LANGUAGE*.

ITALIAN coins, measures, medals, &c. See *the* *Italian* *monies*.

ITALIC, or *ITALIAN Hours*, are the twenty-four hours of the natural day, accounted from the sun's rising on the day, to the same again the next day.

This way of reckoning was used by the Jews, and is used by the *Italians* to this day.

ITALIC character, in *Printing*. See *LETTERS*.
ITALIC sect, is the name of a party of a sect of philosophers, founded by Pythagoras; so called, because the philosopher taught in Italy, spreading his doctrine among the people of Tarentum, Metapontus, Heraclea, &c.

ITCH, a distaste of the skin, wherein it is attended with the coming out of certain sharp saline humors, which gather into pustules, and occasion a pruritus. The *pustula* or *itch* is described by Celsus as consisting in hardness and roughness of the skin, from the coming out of pustules thereon; some drier, other moist, and coming out a fœtid matter, which occasions a constant itching.

These eruptions are most frequent about the joints of the limbs, and between the fingers; they spread over the whole body; in others they are confined to the face, and in some they return at certain seasons of life.

In youth, this distaste frequently prevents the cure of them.—But it sometimes degenerates into a more dangerous kind, a *lepra*, and a *scab*.

ITCH, form of the. The most obvious and general form of the *itch* are the eruptions of pimples, or pustules, over the whole surface of the body, excepting only the face, which contain, in the end, a fœtid and ulcerous matter. These pustules usually appear first in the hands, and in other parts as are most exposed to the air, and from there gradually spread themselves all over the body. The body is more turgent in those places where the eruptions are situated, than in a state of health; and the patient is attended with a violent itching, especially at night. After a few days they either break out, or are opened by scratching, and then become little ulcers; these, however, usually heal in a very little time, and leave no fear behind. This kind of benign *itch* occupies no part of the system, and indeed the matter always lies between the cuticle, whence the curia not being deep, the cuticle easily heals.

In the *benign moist itch*, the pustules contain a quantity of matter, and when broken discharge a quantity of it; there is also round the basis of the pustule a kind of inflammatory red circle; and, in this kind, it appears, the greater is the suppuration, the more the pustules rather give a sensation of pain than that of itching.

In the *benign dry itch*, the pustules are much smaller, and are full of a limpid water, which dries, and leaves the skin more superficially, and occasions a constant itching, rather than any soreness or heat in the skin.

The *malignant itch*, when of the ferine kind, is attended by some of the ferocious *itch*, is dry and scaly, and is attended by bloody spots under the larger scales, and round about these is tinged with the ferine color. Sometimes to a red, sometimes to a livid, and sometimes to a blackish color. The itching from this kind is more violent than from the benign, and on any part of the body, either to hotter or colder, is more intolerable. When the scabs and crusts are scratched off, as is very frequently the case, the cutis underneath is seen red and bloody, but neither blood nor lymph are discharged from the scabs in some cases, in others a yellowish ferous liquor runs out, and almost immediately hardens into a scab or crust like that which was pulled off.

ITCH, the venereal or psori. This is usually rather dry than moist, and does not spread itself so quickly as the other kinds. It sometimes occupies the body in general, sometimes only particular places, as the thighs, the scrotum, or the face. At its first appearance there are usually felt certain little tumors under the skin; and after this there appears a scab which remains on the part a considerable time, and will not easily be removed or torn off. The pain of this is sharp and excruciating, especially when it is exacerbated by scratching; and while this is fixed to some one part, there are pains felt deep within the flesh in other places, which are most intolerable in the night; and in women the floor albus, or whites is usually an attendant on it; and in men sometimes a gonorrhœa, sometimes bubos and other tumors; and in infants, who are thus affected, from the diseases of their parents, there are frequent excoriation, and often crillated and varicose excrescences of flesh about the anus.

ITCH, the leprous. In this the head is frequently affected, the pains are very violent, and the hair and skin very frequently

institution, and the same ceremony was observed in all their houses throughout the world.

JUBILEUS, or **JUBILEUS**, is used among the Romanists, to signify a religious who has been fifty years in a monastery, or an ecclesiastic who has been in orders fifty years.

Such veteran religious are dispensed with in some places from attending matins, or a strict observation of any other of their rules.

JUBILEUS is also extended to any man a hundred years old; and to a possession, or prebend for fifty years. *Si ager non incensatur in scriptis, inspiratus de fœderibus, quantum temporis fuit cum altero? & si fœd. certo jubileo manet sine usurpatione, manet in æternum.*

JUCADICE, *arbor*, in *Betay*, a name by which some authors have called the *canela alba*, or wild cinnamon-tree.

JUCCA, in *Betay*, the name of a distinct genus of plants otherwise called *TUCCA*.

JUCKING, the notes of a cock partridge, inviting the hen to come to him. These serve the sportsmen in good stead for finding the places where they are.

JUCURUTA, a very beautiful species of owl, found in the Brazil, and variegated with black and yellow.

JUDÆ, *arvicola*. See **ARVICOLA**.

JUDAICUS lapis, a small, grey, soft, brittle stone, in form of an olive, having lines drawn regularly on its surface, as if they were formed by art. *Tab. III. Figs. 10.* It is of some use in physic; being supposed to be endowed with a lithontriptic power; and therefore is given to dissolve the stone in the bladder. It is a kind of extraneous fossil, being a spine of an echinus marinus petrified. This stone has by many been supposed to be a fossil body in its native figure, but is really the remains of a spine of an echinus, filled with a plated spar. It is very common in Syria, and is sometimes found with us.

See **SPAR**.

JUDAISM, the religious doctrine and rites of the Jews. *Judaism* was but a temporary dispensation, and was to give way, at least the ceremonial part of it, at the coming of the Messiah. For a complete system of *Judaism*, see the books of Moses. *Judaism* was anciently divided into several sects; the principal whereof were the Pharisees, Sadducees, and Essenians.

At present there are two sects among the Jews, viz. the Caraites, who admit of no rule of religion, but the law written by Moses; and the Rabbinites, who add to the law the traditions of the Talmud.

It has been observed, that *Judaism*, of all religions, is that which is the most rarely abjured. In the 18th of Edward I. the parliament granted the king a fifth part for the expulsion of *Judaism*.

In England, formerly, the Jews and all their goods belonged to the chief lord where they lived, and he had such absolute property in them, that he might sell them; for they had no liberty to remove to another lord without leave. *Mat. Paris* tells us, that Henry III. sold the Jews to earl Richard his brother, for a term of years, that *quis rex christianorum, comes christianorum*. They were distinguished from the Christians both living and dying; for they had proper judges and courts where in their causes were tried, and they wore a badge on their breast over their cloths in shape of a table; and they were fined, if they stirred abroad without such badges. They were never buried in the country, but always brought up to London, and interred without the walls.

JUDAS, *iræ, eris*, in *Biston*, a genus of the *decandria monogynia class*. Its characters are these: the flower has five petals, which are inserted in the empalement, and greatly resemble a papilionaceous flower; the standard is of one roundish petal, and the keel is composed of two petals; it has ten distinct stamina, four of which are longer than the rest; it has a long slender germen, which becomes an oblong pod, with an oblique point, having one cell, inclosing several roundish compressed seeds. There are two species. *Miller*.

JUDDUCK, in *Ornithology*, the name commonly given, in England, to a small species of snipe, called by authors, *gallinago minima*, and in some places with us, the *gad*, or *jack snipe*.

JUDE, or the *Epistle of JUDE*, a canonical book of the New Testament, written against the heretics, who by their impious doctrines and disorderly lives, corrupted the faith and good morals of the Christians. See **EPISTOLA**.

In the early ages of Christianity, several rejected this Epistle, because the apocryphal books of Enoch, and the ascension of Moses, are quoted in it. Nevertheless it is to be found in all the ancient catalogues of the sacred writings; and Clement of Alexandria, Tertullian, and Origen, quote it as written by Jude, and reckon it among the books of sacred Scripture.

Vol. II. N° 190.

JUDGE, an officer appointed by the sovereign powers of any country, to distribute that justice to their subjects which they cannot administer in person.

The character of *judge* is part of the regal authority, whereof the king dwells himself.

The chief function of *judges* is for the trial of causes both civil and criminal.

The English *judges* are chosen out of the sergeants at law, and are constituted by letters patent. Their commissions are bounded with this limitation, *facti quod ad ipsos pertinet secundum legem & consuetudinem Angliæ*; and at their creation they take an oath, that they will indifferently minister justice to all them that shall have any suit or plea before them; and this they will not forbear to do, though the king by his letters, or by express word of mouth, should command the contrary; and they are answerable in body, land, and goods. 18 Ed. III. c. 1.

By the law of England all *judges* must derive their authority from the crown, by some commission warranted by law. The *judges* of the king's bench, common pleas, and the barons of the exchequer, are all (excepting the chief justice of the king's bench, who is created by writ) appointed by patent. Formerly they held their places only during the king's pleasure; but now, for the greater security of the liberty of the subject, by statute 13 Will. III. c. 2. their commissions are to be *quandiu bene segerint*, and their salaries are ascertained and established; and by 1 Geo. III. cap. 23. they are to continue, notwithstanding the demise of the crown; and their full salaries are absolutely secured to them during the continuance of their commissions. Though upon an address of both houses of parliament, they may be lawfully removed.

Judges must exercise their authority in a legal manner and hold their courts in their proper persons, for they cannot act by deputy, nor any way transfer their power to another, as the *judges* of ecclesiastical courts may. Yet when there are several *judges* in a court of record, the act of any one of them is effectual, provided these commissions do not require more; so likewise what is executed by a majority present, is the act of the court; but where they are equally divided in opinion, the cause is to be removed into the exchequer chamber, and for that purpose a rule is to be made, and the record certified, &c. Some things done by *judges* at their chambers, are accounted as done by the court; and that they may be prepared to hear what is to come before them, they are to have a paper of the causes to be heard, sent to them by the attorneys the day before they are spoken to; that if, upon reading the record of any cause, any special matter that arises should appear doubtful, they may satisfy themselves by consulting books.

The *judges* are bound by oath to determine according to the known laws and ancient customs of the realm. Their rule herein must be the judicial decisions, and resolutions upon the various causes that have occurred, and not their own arbitrary will and pleasure, or that of their prince.

Judges are free from all prosecutions for any thing done by them in court, which appears to have been an error of their judgment. But for wilful corruption, they have been complained of to the bar-chamber formerly, and may now be called to an account in parliament.

It has been said, that scandalous reflections on the *judges* in Westminster-hall are within the statute of *scandalum magnatum*.

Those who use threatening or reproachful words to a *judge* sitting in the courts, are guilty of a high misdemeanor, and have been punished with fine, imprisonment, and corporal punishment. Assaulting a *judge*, sitting in the court, by drawing a weapon, without any blow struck, is punishable with the loss of the right hand, imprisonment for life, and forfeiture of goods and chattels, and of the profits of the person's lands during life; and slaying the chancellor, treasurer, or the king's justices of either bench, justices in eyre, or justices of assize, and all other justices assigned to hear and determine, being in their places during their offices, is a species of treason by 25 Edw. III. c. 2. However the barons of the exchequer, as such, are not within the protection of this act. *Judges*, who become solicitors in a cause which they are to judge, and privately and extrajudicially tamper with witnesses, or labour jurors, may be dealt with according to the same capacity to which they basely degrade themselves. Bribery in *judges* is punishable by loss of office, fine, and imprisonment; and by the common law, bribery of *judges* in relation to a cause depending before them, has been punished as treason. If a *judge* ignorantly condemns a man to death for felony, when it is not felony; for this offence he shall be fined and imprisoned, and lose his office. If a *judge* who hath no jurisdiction of the cause, give judgment of death and award execution, which is executed, such *judge* is guilty of felony; and also the officer who executes the sentence. And if justices of the peace, on indictments of trespass,

treasures, arrange a man of felony and judge him to death, and he is executed, it is felony in them. A judge ought not to judge his own cause, *in propria persona* where he is party. It was formerly enacted, that 23 Hen. VIII. c. 24, that none should be justice of assize within the county where they were born, or so inhabitable; but this is repealed by a late statute, 12 Geo. II. c. 27. It was formerly held that by a justice's acceptance of any new name of dignity, his commission was determined; but this was remedied by statute 1 Edw. VI. c. 7. But it has been doubted, whether the dignity of baronet, created since that statute, is within the equity of it.

JUDGES, LIBERTY. See **LIBERTY.**

JUDGES, IN SCRIPTURE, is applied to certain eminent persons chosen by God himself to govern the Jews, from the time of Joshua till the establishment of the kings.

The Hebrews were governed by fifteen judges, for the space of 340 years. viz. from the time of Othniel their first to that of Samuel their last judge.

The judges were not ordinary magistrates, but were appointed by God on extraordinary occasions, as, to lead the armies, to deliver the people from their enemies, &c. — Salian has observed that they not only presided in courts of justice, but were also at the head of the councils, the armies, and of every thing that concerned the government of the state; though they never assumed the title either of princes, governors, or the like.

In some respects they resembled kings; viz. 1. In that their authority was given them for life, and not for a limited time. 2. They ruled alone, and without any dependency; which occasioned Josephus to call their state monarchies.

Salian remarks seven points wherein they differed from kings. 1. They were not hereditary. 2. They had no absolute power of life and death, but only according to the laws, and dependently upon them. 3. They never undertook war at their own pleasure, but only when they were commanded by God, or called to it by the people. 4. They exacted no tribute. 5. They did not succeed each other immediately, but after the death of one there was frequently an interval of several years before a successor was appointed. 6. They did not use the ensigns of sovereignty, the sceptre or diadem. 7. They had no authority to make any laws, but were only to take care of the observation of the laws of Moses.

JUDGES, or book of JUDGES, is a canonical book of the Old Testament, containing the history of the Israelite judges, whereof we have been speaking.

The author is not known; it is probable the work did not come from any single hand, being rather a collection of several little histories, which at first were separate, but were afterwards collected by Esdras, or Samuel, into a single volume; and in all likelihood, were taken from the ancient journals, annals, or memoirs, composed by the several judges.

JUDGMENT, a faculty of the soul, by which it perceives the relation between two, or more, ideas.

Thus, when we judge, that the sun is greater than the moon, the understanding first compares the two ideas of the sun and the moon; and, finding the idea of the sun greater than that of the moon, the will perfectly acquiesces in that perception, nor puts the mind upon any farther enquiry.

It is not the understanding then that judges, as is ordinarily thought; judgments and reasonings on the part of the understanding, are but mere perceptions; it is the will alone that judges, by acquiescing in what is represented to it by the understanding.

The only difference then between perception, judgment, and reasoning, so far as the understanding is concerned in them, is this: that it perceives a thing simply, without any relation to any other thing, in a simple perception; that it perceives the relation between two or more things, in judgments; and, lastly, that it perceives the relations that are between the relations of things in reasonings; so that all the operations of the understanding are in effect no more than pure perceptions.

Thus, when we perceive, for instance, twice 2, or 4, this is no more than a simple perception; when we judge, that twice 2 are 4, or that twice 2 are not 5, the understanding does no more than barely perceive the relation of equality that is between twice 2 and 4, or of inequality between twice 2 and 5. Further, reason consists in perceiving the relation, not between two or more things, but that would be a judgment, but of two or more relations of two or more things: thus, when I conclude, that 4 being less than 6, twice 2 being 4, are by consequence less than 6; I perceive not only the relation of inequality between 2 and 4, and 6 (for this were only a judgment), but also the relation of inequality between the relation of twice 2 and 4, and the relation between 4 and 6; which constitutes a reasoning. The

understanding therefore only perceives, and it is the will that judges and reasons, in assenting voluntarily to what the understanding represents.

Indeed, when the things which we consider appear clear, and perfectly evident, it seems as if it were not voluntarily, that the mind consents to them; whence we are led to think, that it is not properly the will, but the understanding that judges of them. — But to clear this point, it must be observed, that the things which we consider, never appear entirely evident, till the understanding has examined them on all sides, and has perceived all the relations necessary to judge of them; whence it happens that the will, not being able to will any thing without knowledge, cannot act on the understanding; that is, cannot desire it to represent any thing new in its object, as having already viewed it on all sides that have any relation to the question in hand. It is obliged then to rest in what has been already represented, and to cease to agitate and disturb it any farther; in which cessation it is, that judgment consists.

This rest or judgment, then, not being free when things are in their last evidence, we are apt to imagine, that it is not the effect of the will. So long as there is any thing obscure in the subject that we consider, or that we are not fully satisfied that we have discovered every thing necessary to resolve the question, as it happens in most of those things that are difficult, and that contain various relations; we remain at liberty not to acquiesce: the will may command the understanding to pursue its enquiries farther, and to make new discoveries, whence it is, that we are more ready to allow the judgment formed on these subjects to be voluntary.

Most philosophers, however, maintain, that even the judgments which we form on obscure things are not voluntary; and will have our consenting to the truth to be an action of the understanding, which they call *assent*, to distinguish it from our consenting to goodness, which they attribute to the will, and call it *consent*.

But their error is owing to this, that in our present state we frequently see things to be evidently true, without the least reason to doubt of them; in which case the will is not at liberty either to give or refuse her assent: but it is not so in matters of goodness; there being nothing, which we do not know some reason for forbearing to love. So that we here perceive a manifest indifference and are fully convinced, that when we love any thing, even God, for instance, we use our liberty, and do it voluntarily. But the use we make of our liberty is not so apparent, when we consent to the truth, especially when it appears perfectly evident; and this leads us to think, that our consent to truth, that is, our judgment is not voluntary; as if an action, to be voluntary, must be indifferent; as if the blessed above did not love God voluntarily, because they cannot be diverted from it by any other thing; nor we consent freely to this evident proposition, that twice 2 are 4, because we have no appearance of reason to dissuade us from it.

JUDGMENT, in a Legal Sense, is a sentence or decision pronounced by authority of a king, or other power, either by their own mouth, or by that of their judges, and officers, whom they appoint to administer justice in their stead.

Of judgments, some are definitive, others only preparatory, provisional, or interlocutory. See **DEFINITIVE, INTERLOCUTORY,** &c.

The ancient words of judgment are very significant. *Consideratum est*, &c. because judgment is ever given by the court, upon consideration had of the record and matter before them. — In every judgment there ought to be three persons, *actor, reus, and judex*; plaintiff or prosecutor, defendant, and judge.

JUDGMENT may be given not only upon the trial of the issue, but on a default, confession, demurrer, or an outlawry, which is a judgment in itself. After issue joined in a cause, the plaintiff may, if he thinks proper, accept of a judgment from the defendant; but on such a judgment, a writ of error may be had without putting in bail, which cannot be done on a judgment after verdict. — All judgments given in courts of record must be entered; in order to which the plaintiff's attorney, four days after the record is brought into court, may, if the judgment is out, enter judgment by the usual course of the court; but he cannot do this sooner, because the defendant must have time to bring in a writ of error, or to finish out matter for an arrest of judgment. The defendant may oblige the plaintiff to enter his judgment, in order that he may plead it to any other action; and judgment upon a demurrer to a declaration, &c. which does not pass upon the merits of the cause, is no bar to it, though other judgments may be pleaded in bar to an action brought again for the same thing. Judgments are to continue till they are reversed; but an action of debt will lie on a good judgment,

as well as a writ of error is brought, as before it. If a plaintiff does not take out an execution within a year and a day after judgment is obtained, the judgment must be reversed by a *SCIRE FACIAS*.

JUDGMENTS for crimes, in case of treason or felony, must be by an express sentence, an outlawry or abjuration; and no judgment can be indicted contrary to law, or that is not appointed by act of parliament. These judgments are of very different kinds; as in high treason the offender is sentenced to be drawn, hanged, his entrails taken out and burnt, his head cut off, and his body quartered, &c. In petit treason the judgment is, to be drawn to the place of execution, and there hanged. But a woman in all cases of high and petit treason, is to be drawn and burnt. All persons, for felony, are to be hanged by the neck till dead. Judgment in misprision of treason, is imprisonment for life; and for misprision of felony, the offender is subject to a fine and imprisonment; and for crimes of an infamous nature, the judgments are discretionary in the breast of the court, and those guilty are punished by a fine, pillory, &c. See *EXECUTION of Criminals*.

JUDGMENTS for debts, are acknowledged by a person giving a general warrant of attorney to any attorney of the court in which it is to be acknowledged, to appear for him at the suit of the party to whom the same is to be done, and to file common bail, receive a declaration, and then to plead *non sum informatus*, I am not informed, or to let it pass by *nila dicit*, he says nothing; upon which judgment is entered for want of a plea. Judges that sign judgment of lands, are to set down the day of the month and year in which they do it; and they shall be good against purchasers only from such signing. Where a person has acknowledged a judgment for the security of money, and afterwards on borrowing more money of another person, mortgages his lands, &c. without giving any notice of the judgment to the mortgagee; in such case, if the mortgagee do not within six months pay off and discharge the judgment, he shall forfeit his equity of redemption, 4 and 5 Will. and Mary. Acknowledging a judgment in the name of another person without his privity or consent, is made felony, by 21 Jac. I. c. 26.

JUDGMENT, *Arrest of*. See *ARREST*.
JUDGMENT, *Affidavit falsi*. See *ASSIGNING*.
**JUDGMENT of God. See *JUDICIUM Dei*.
JUDGMENT, *Mistake of*. See *MISTAKE*.
JUDGMENT, *Villainous*. See *VILLAINOUS*.
JUDICATURE, the quality, or profession, of those who administer justice.**

In which sense *judicature* is a kind of priesthood.—In France, offices of *judicature* are venal.

JUDICATURE is also used to signify the extent of the jurisdiction of the judge, and the court wherein he sits to render justice.

JUDICE.—*Coram non JUDICE*. See *CORAM*.
JUDICIAL. See *EXTRAJUDICIAL*.
JUDICIAL Astrology. See *ASTROLOGY*.
JUDICIAL Oratory. See *ORATORY*.

JUDICIALIS Lex. See *LEX*.
JUDICIARY Astrology. See *ASTROLOGY*.
JUDICIARY Deposit. See *DEPOSIT*.
JUDICIO Falso. See *FALSO*.

JUDICIUM Dei, JUDGMENT of God, was a term anciently applied to all extraordinary trials of secret crimes; as those by arms, and single combat, and the ordeals; or those by fire, or red-hot ploughshares; by plunging the arm in boiling water, or the whole body in cold water; in hopes God would work a miracle rather than suffer truth and innocence to perish.

Si super defendere non possis, judicio Dei, scilicet, aqua vel ferro fieri de eo iudicabis.

These customs were a long time kept up, even among Christians; and they are still in use in some nations. See *ORDEAL*, *WATER*, *COMBAT*, *DUEL*, and *CHAMPION*.

Trials of this sort were usually held in churches, in presence of the bishops, priests and secular judges; after three days fasting, confession, communion, and many abjurations and ceremonies, described at large by Du Cange.

JUDICIUM Afflicti. See *ASSISE*.

JUDICIUM Parium denotes a trial by a man's equals, i. e. of peers by peers, and of commoners by commoners. In *magna charta* it is more than once insisted on as the principal bulwark of our liberties, but especially by chap. 29. that no freeman shall be hurt in either his person or property, nisi per legale iudicium parium suorum vel per legem terræ. And this was ever esteemed, in all countries, a privilege of the highest and most beneficial nature.

JUFFERS, among carpenters, a term used for pieces of

wood about four or five inches square, and of several lengths.

JUG, an earthen pot or pitcher to hold drink; also a term used in many parts for a common, pasture, or meadow.

JUGERUM, a Roman measure, the double of the *actus quadratus*. It was a square of 120 Roman feet. The *jugerum* was divided into 12 *asses*, and the *uncia* into 24 *scrupula*. Its proportion to the English acre is as 10000 to 16667.

JUGLANS, in *Botany*. See *WALNUT TREE*.

JUGLERS. See *PROVENÇAL POET*.

JUGULAR, among *Anatomists*, is applied to certain veins of the neck, which terminate in the subclavian. See *VEIN*. The *jugular veins* are two on each side; the one *external*, receiving the blood from the face, and the external parts of the head; the other *internal*, which receives the blood from the brain. See *Tab. Anat. (Jugalis)* fig. 6, Lit. B. H.

JUGULAR is also applied to certain glands in the neck, in the spaces between the muscles.

The *jugular glands*, are in number fourteen; they are of different figures, some larger, others less; they are fallen to each other by certain membranes and vessels; and their substance is like that of the maxillaries.

They separate a lymph, which is conveyed by those vessels to the adjacent muscles. It is an obstruction in these glands which occasions the king's evil.

JUGULARES, in the *Linnæan System*, is the name of an order or division of fish, the general character of which is, that they have ventral fins before the pectoral fins. This order comprehends five genera, viz. *calispermus*, *transiparus*, *trachinus*, *gobius*, and *bleinnius*, and thirty-five subordinate species.

JUICE, a liquid substance, which makes part of the composition of plants; being diffused among all the solid parts, and serving for their nutriment and growth.

The *juice*, or *sap*, is that to *PLANTS*, which blood is to animals. See *Juice of PLANTS*.

There are *juices* of divers kinds, *aquous*, *viscous*, *oleaginous*, *gummeous*, *resinous*, and *bituminous*; and of all tastes and colours.

JUICE, *Spanish*. See *LICORICE*.

JUICE is also applied to several, and even to all, the fluids, or humours, in an animal body.

JUICE, *nervous* and *pancreatic*. See the adjectives.

JUICE is also applied to the vapours and humidities enclosed in the earth.

Thus crystal is said to be formed of a lapidific *juice*, and metals to be generated of vapours and *juices* condensed in the earth.

JUICES, *concrete*, in *Mineralogy*, a name given by many authors, to such substances found in the bowels of the earth, as have once been in a state of fluidity, and are capable of being rendered fluid again by air, by means of heat, moisture, or other common agents.

Others apply the word *concrete* to all those substances which may be separated from fluids by chemical operations, whether they are afterwards soluble in them again or not; such are the particles of spar, separated from water by a slow distillation, and remaining at the bottom of the vessel.

The *concrete juices* of the earth are supposed to be the principal things which give the virtue to mineral waters; for those which receive no concretions, and are only mingled with the water in their passage through that part of the earth where they are evaporated, on the water's being exposed to the air, though they may give a briskness to it, while entire in it, yet are not to be supposed to give the principal virtues. These fluid and volatile *juices* all fly off in the analysis of the waters, but the *concrete juices* are more permanent, and leave certain sediments which render them visible and palpable, after the distillation of the waters with which they are mixed.

When these happen to be simple, and of the same species with those known in a solid state, it is easy to deduce the virtues of the waters from them, and to know what must be the effect of such fluids as carry spar, sulphur, vitriol, or other well-known substances, into the blood; but it seldom happens that these things are thus contained simple and entire in the waters, they are often blended variously with one another, and often not the whole of the known body is contained; but the principles that constitute some part of it, such as the acid of vitriol without its metalline part, the basis of the sea-salt without its acid, and so of the rest.

Salts and earths are evidently the most sensible and the most common matters which are mixed with water, and it is from them in general that the medicinal springs take up their virtues. There is scarce any earth that does not contain some sort of mineral salt, capable of being washed out by water, though it is generally in imperceptible quantities; but where the earths are richer in these salts, the waters not only take them up, but carry also with them the several finer particles of the earth itself in

which they are bodied, and rising up at some small distance from the place, they make medicinal springs, of virtues answerable to the peculiar species of the salt that was lodged there. We are always able to separate, by analysis, the salts and the earths of the mineral waters; but when we have done this, we are not arrived at the end of the task, for they are often such mixed substances, that we can neither know them perfectly as they are, nor separate them.

The four most common, and frequent of those concrete juices which are called salts, are alum, nitre, vitriol, and culinary salt; but the examination of the water of different medicinal springs shows us, that there are in the earth others very different from these, and that perhaps in great numbers. There is in Asia a native alkali salt, or natrum, and in all the mineral waters we celebrate, there is a peculiar salt separable by evaporation, which is nearer allied to this than to any of the other four, to one or other of which it has been the custom to reduce all salts; and yet different even from this in some respects. Beside this, those *juices* of the saline kind, whose disposition to concretion is not yet finished, and whose state is, as it were, but in embryo, or the first stage of being, are not to be known, when separated from the waters to which yet they may have perhaps given virtues greater than the concrete, in what we call its more perfect state, might have given: nay, even those that are more formed, and are already concreted, or in a state capable of concretion, have not simple and homogeneous substances in each of the species. The salt that is called culinary salt, is observed to have two different portions mixed together, the one is condensed and crystallized by cold and in moisture, after the evaporation of a part of the water wherein this salt has been dissolved; and the other will not be crystallized nor condensed, but by a total evaporation of the water. The portion of this salt that is crystallized by cold and in moisture, is the most sulphureous; and by its sulphureity it will mix itself with the sulphurous salt of calcined tartar resolved in a moist air, or in common water, without turbidness, and without coagulation; but that portion of this common salt which is not condensed but by the total evaporation of the water which had dissolved it, hath an acidity which instantly coagulates the salt of tartar dissolved, and all other salts in the same state which are sulphureous and nitrous. It is evident, that while this salt is in its embryo state, the one or the other alone of these two very different substances of which it is contained, may be mixed with the waters of a spring, and communicate virtues different from those which the whole body of the salt would have done. This salt also being procured by evaporation of the water, or by any other analysis of it, could not be known or referred to the common salts, and much less if in the earth, as may very easily happen, it should be united with some one of the constituent parts of some other salt, in the same dissipated or unfashioned state.

The vitriol which in a moist air yields an efflorescence upon sulphurous maracites, has likewise a juicy portion, condensable only by a total evaporation of its aqueous humidity; this is of a very acrimonious taste, of an unctuous substance, and easily runs to water in a moist air. This juicy portion of vitriol is very different from that which thoots and condenses in the fluid liquor, by means of the cold. These crystals are pure vitriol acid, austere, and on being mixed with the sulphurous and nitrous salts, a great quantity of earthy matter precipitates out of them; but the other portion will mix itself with these salts in solution, without turbidness or emulsion, not having, like the former, that acidity upon which the sulphurous or nitrous salts can act which is exactly contrary to what happens to common salt, of which the first portion is the most sulphurous, and the latter portion the most acid. Nitre is also, like the rest, composed of two different saline portions, the one more sulphurous, which crystallizes with the cold, and in moisture, and the other, which remains dissolved after all the crystals are obtained, and which cannot be obtained in a dry form, but by the evaporation of all the humidity. This is less sulphurous than the other part obtained in crystals, and has some acidity which the other has not.

The first embryos of mineral salts are nothing else but exposures or *juices* not concreted, but totally volatile or vaporable; of these some may be condensed, and in part fixed by the action of fire, or disengaged from their matrices, and made capable of concretion by means of the air, as is observed in certain nitrous, aluminous, and vitriolic salts. The sulphurous part, which is formed in the lime, made of certain hard stones burnt in the fire which is generally allowed to be a species of nitre, has certainly its seminal being in these crude stones, and in

that state of its being, is very different from that which we find after it has passed the fire, which from cold and coagulative, changes into caustic and resolute. This cold and coagulative quantity of this stony salt, in its first state, manifests itself sufficiently in the waters of certain rock springs, which are very limpid and cold, and breed cold and ferocious tumors under the throats of those people who ordinarily drink them, as in the Alps, &c. See BAONCHOCLE.

The seminal matter of this salt then is wholly altered in its nature by fire, and is rendered sulphureous and caustic as nitre. Fire is able to exalt and alter the state of being of this salt, but it is no more able to produce it in these stones, than in the shells of oysters, &c. of which also a lime is made, which yields a salt not more sulphurous than this. Du Clos, *Observ. sur les Eaux Min.*

The seminal being of alum and vitriol must, in the same manner, exist in those substances out of which those salts are extracted by water, after they have been calcined by fire, or exposed to a slower calcination in the open air. They are not found in these stones before these processes, yet it is sufficiently evident that the fire and air could not produce them, but could only exalt them there.

All these varieties to which the several mineral salts are liable in the different stages, and in which they may be absorbed together, and united by water under the earth, do not only render the judging of the mineral waters, which partake of them, by analyses very uncertain, but even, in many cases, perplex and confound us, by the very means by which we hope to understand them.

JUICES, mineral. Many countries afford these, and give marks by them of treasures that might be turned to great account, were the proper manner of assaying them known, which is by first properly reducing them to a dry substance, so as to come at the solid matter they contain. With a view to the discovery of metallic veins, the erection of salt-works, vitriol-works, alum-works, borax-works, and the like, the curious on this subject may find many excellent hints for farther discoveries in the close of Agricola's work, *De Re Metallica*; and the view is further carried on by Boyle, Becher, Stahl, and Homberg. The Royal Academy of Paris have also given some hints that may be of use, in their Memoirs; and some practical things are recorded in the Philosophical Transactions. We have accounts in the Philosophical Transactions, of white and thick fluids like cream, found in mines at very great depths, and containing mineral particles. The bottoms of our coal-pits sometimes afford this liquor in very large quantities. And some of the iron mines in Shropshire, particularly that called the White-Mine near Hales in that county, affords a great quantity of this sort of juice. It is thick as cream, white, and of a sweetish taste, but with a vitriolic tinge behind it. This is contained in the nodules of iron stone, which are here a sort of chrydri, very large, composed of thick crusts, and some of them holding near a hoghead of this sort of liquor. Phil. Trans. N^o 100. See ENHYDROS.

JUUSE, or JUUS, juniperus, in Botany. Its characters are these: the flower has no empaleme, but has one funnel-shaped petal, which spreads open at the top, and is cut into four or five segments; it has five awl-shaped stamens, whose bases are inserted into the petal, and are terminated by small summits; it has an oval germin supporting two slender styles, crowned by obtuse stigmas and which becomes an oblong oval berry, inclosing a single nut of the same form, which has two cells, each containing an oblong seed. There are four species, natives of the East, and of the warm parts of Europe, which are preserved in the gardens of the curious. They are propagated by planting their stones in pots of light earth, soon after the fruit is ripe, and in winter they should be preserved under a common hot-bed frame, where they may be defended from the severer frosts, and in spring the pots should be plunged into a moderate hot-bed. When the young plants are come up, they should be enured to the open air by degrees, and in June they may be removed out, and placed under the shelter of a warm hedge. In this place, they should remain till the beginning of October, when they are to be removed into the green-house, or else placed under a hot-bed frame, that they may be preserved from the frosts. During the winter they should have as much air as the season will permit, and be watered at times, though this must be very cautiously done, after they have shed their leaves. In the March following, before they begin to shoot, they are to be transplanted each into a separate pot of light earth, and they should then be plunged into a moderate hot-bed, and watered and shaded till they have taken thorough root; and in May they are to be removed thence into the open air. They must be housed in winter till they are about four years old, and then may be transplanted into the naked ground, and will stand our winters. Miller.

The *zephyrus*, according to Linnaeus, is only a variety of rhomus, with oval leaves, and two styles; the fruit, or nucleus of which, contains two cells, and its corolla has five fragments. See *Buxifolius*.

It is a native of Spain and Italy; and the fruit, which is of the figure of an olive, and reddish when ripe, was once esteemed as a pectoral, and sometimes prescribed in fevers; but is discredited in the present practice. In Italy and Spain this fruit is served up at the table in salads, during the winter season, as a dry sweetmeat.

JULEP, or **JOLAR**, *JOLARIE*, in Pharmacy, and described according to Meissner, from the Arabic *julep*, or rather from the Greek *zulewer*; Osius derives it from *julp*, a Persian word, signifying *refreshment*; is an easy, agreeable, extemporaneous potion, mixed with sick persons; usually composed of camomile-water, or simple distilled water, with one third or one fourth its quantity of distilled spirituous water, and sweetened with sugar or proper syrup. This is in this potion with vegetable or mineral acids, or interperated with other medicinal *juleps* are sometimes used as the vehicles of strong medicinal doses, but more usually for a vehicle for other forms of medicines; serving chiefly to dilute, to correct the acrid humours, relieve the distending force of the heart, and promote sleep.

In dysenteries, we have several different *juleps*; the principal of which are,

JULEP, *campari*, *julep* *camphora*, a medicine prescribed in the late London Dispensatory, and seeming the best calculated of any thing of the kind, to communicate the virtue of camphor to water. It is made thus: take camphor, a dram; fine sugar, half an ounce; boiling water, a pint; grind the camphor with a little spirit of wine till it is softened, then add the sugar, and by degrees perfectly unite them; finally add the water by a little at a time, and when the whole has stood in a covered vessel till it is cold, strain it off.

Others direct the *ambrosiated julep* to be made by grinding one dram of camphor with a little spirit of wine, then adding half an ounce of gum arabic reduced to a mucilage, with an equal quantity of water, and rubbing them together till they are perfectly united. To this mixture add, by little and little, a pint of vinegar, with an ounce of double-refined sugar dissolved in it, till continuing the trituration. This *julep* may be taken in the dose of a spoonful or two, in hysterical and other complaints where CAMPHOR is proper.

The *crystal julep* is made, by mixing four ounces of simple cinnamon-water, two ounces of Jamaica pepper water, volatile aromatic spirit, and compound spirit of lavender, of each two drams, and an ounce of syrup of orange-peel; and is given in the dose of two spoonfuls, three or four times a day, in disorders accompanied with great weakness and depression of spirits.

The *expectorating julep* is formed, by mixing four ounces of the EMULSION of gum ammoniac with two ounces of the syrup of figs. Two table-spoonfuls of this *julep* may be taken every three or four hours in coughs, asthma, and obstructions of the breast.

Milk julep is made, by rubbing half a dram of musk, and half an ounce of sugar together, and adding gradually two ounces of simple cinnamon-water, and as much of peppermint-water, and also two drams of the volatile aromatic spirit. Two table-spoonfuls of this *julep* may be taken every two or three hours, in a low state of nervous fever, hiccuping, convulsions, and other spasmodic affections.

The *saline julep* is prepared by dissolving two drams of salt of tartar, in three ounces of fresh lemon juice, strained; when the effervescence is over, add of mint-water, and common water, each two ounces, and of simple syrup one ounce. This *julep* removes sickness at the stomach, relieves vomiting, promotes perspiration, and may be of service in fevers, especially of the inflammatory kind.

The *vomiting julep* is made, by dissolving four grains of emetic tartar in eight ounces of water, and adding to it half an ounce of the syrup of clove *july-flowers*. This *julep* may be given, in the beginning of fevers, in the dose of one table-spoonful every quarter of an hour till it operates. BACON.

MEPHITIC julep. See PYRAMONT water.

JULIA, in *Nitidophora*, a name given by Salvia and Gera, to the *iris* of the Greeks, called *julia* by the Latin writers in general, and by the Italians, *davallina*. It is a species of the *LABRUS*, according to Arted, and is distinguished by that author from the other fish of that kind, by the name of the variegated labrus of a palm long, and having two larger teeth in the upper jaw.

JULIAN calendar, *epocha*, and *period*, see the SUBJUNCTIVE.

JULIAN law. See PAPYRUS *MAN LAW*.

JULIAN year. The *Julian* is the old account of the year, used among us in England till 1752. It is so called from its founder Julius Cæsar; and by that name is distin-

guished from the year, or Gregorian account, used in most parts of Europe. See YEAR.

JULY, in Botany, the *Month JULY*.

JULY, in *Botany*, the name of a small fish, a species of the *LABRUS*, caught principally near Oporto, and sold in the market, being a very delicate eating fish. Its whole size is about the length, and a little more than the breadth of a finger. The males of this species are very beautifully painted. Their backs are green and their heads have variegations of yellow and red. The sides have very broad variegated lines of a fine gold yellow, and the back fin has several large spots of blue and red. They are fond of human blood, and will seize upon the legs of people who walk naked into the water.

JULUS, *JULUS*, derived from *JUL*, whence *JUL*, a *flow*, in *Antiquity*, an ancient hymn sung by the Greeks, and, after them, by the Romans, during the time of their harvest, in honour of Ceres and Bacchus, to render their deities propitious.

This hymn was sometimes also called *Dionysius*, or *Dionysius*, that is, *Julius* of Ceres.

JULUS, in *Botany*, is a name given to those worm-like tails, or palms (as they are called in willows), which, at the beginning of the year, grow out, and hang pendulous down, from hazels, walnut-trees, oaks, chestnut-trees, mulberry-trees, alders, &c. and are by in popularly called CATKINS.

Mr. Ray observes, that they are collections of the stamens of the flowers of the tree; because in fertile trees and plants, they have abundance of seminal apparatus; which opinion is adopted by Bradley, who makes them to be the male blossoms, and to serve to impregnate the rudiments of the fruit, or female blossoms, which appear on the same trees, or others of the same sort.

JULUS, see GALLUS.

JULY, in *Chronology*, the seventh month of the year, during which the sun enters the sign Leo. The word is derived from the Latin *Julius*, the surname of C. Cæsar the dictator, who was born in it. Mark Antony gave this month the name *Julius*, which was before called *Quintilis*, as being the fifth month of the year, in the old Roman calendar established by Romulus, which began in the month of March. For the same reason, August was called *Sextilis*; and September, October, November, and December, still retain the name of their first rank.

Quæ sequitur, numerus turba natales sui.

On the third day of this month the dog days are commonly supposed to begin, and to end on the eleventh day of August. See CATACULAK day.

JULY, in Botany, or GILLIFLOWERS, in *Botany*, see PINK.

JULY, *flower*, *clive*. See DIANTHUS and PINK.

JULY, *queen's flower*. See DAM'S VIOLET.

JULY, *first flower*. See STOCK, &c.

JUNCAGO, *rust-grass*, in *Botany*, see TRIGLOCHIN.

JUNCI *Lupinus*, in *Natural History*, the name given by authors to a species of fusile corn, of the *tubularis* kind, and composed of a congeries of small tubules, which are usually round and striated within. See *Tub. of Fusiliopsis*.

JUNCO, in *Zoology*, see RUST SPARROW.

JUNCO is also used by Bellinus for a bird, seeming, by its description, the same with what we call the *LYNET*.

JUNCTURE, any joint, or closing, of two bodies. See JOINT.

JUNCTURE, in *Oratory*, is a part of COMPOSITION, particularly recommended by Quintilian, and denotes such an attention to the nature of the vowels, consonants, and syllables in the connection of words, with regard to their sound, as will render the pronunciation most easy and pleasant, and best promote the harmony of the sentence. Thus the coalition of two vowels, occasioning an hollow and obscure sound, and likewise of some consonants, rendering it harsh and rough, should be avoided; nor should the same syllable be repeated at the beginning and end of words, because the sound becomes hereby harsh and unpleasant. The following verse in Virgil's *Æneid* is an example of *junctione*.

Arma virumque cano, Troja qui primus ab oris.

JUNCUS, in *Botany*, see RUSH.

JUNCUS, *aduncus*, see SCHENANTH.

JUNE, the sixth month of the year, during which the sun enters the sign of Cancer. The word comes from the Latin *Junius*, which some derive a *Junius*. Ovid, in the sixth of his *Fasti*, makes the goddess say,

Junius a nostra nomine natus ab oris.

Others rather derive it a *junioribus*, this being for young people, as the month of May was for old ones.

Junius est juncos, qui sunt ante sejun.

In this month is the summer solstice.

JUNGERMANNIA, in *Botany*, the name of a genus of plants of the class *cryptogamia alga*, called by Dillenius, *LICHENASTRUM*, and some of the species are called by Micheli by that name; others by that of *mycodium*.

The characters of the *jungermannia* are these: it produces both male and female flowers, and these are often found both upon the same plant; the male flower stands upon a long pedicle, which arises from a sort of cup or case on the left; this has no cup, no petals, nor any stamina, but is only one single anthera or apex, which is at first of an oval figure, but being composed of four valves, it opens when ripe into four segments, and remains in this state a long time upon the plant; the female part of fructification, as it may be much more properly called than flower, consists only of seeds, so far as we are able to observe, for there is no appearance of either cup or petals; but the seeds are found in some species singly, in others in clusters on different parts of the leaves.

JUNIPA, in *Botany*, the name of a tree of the Caribbee islands, and some other places, the fruit of which is said to yield a juice as clear as water, yet yields a fine violet coloured dye, and being rubbed twice on the same place, makes it black. This tincture, it is said, cannot be got out by soap, or any other method of cleansing, but after nine or ten days disappears of itself. It is said also by the same authors, that hogs and parrots, feeding on this fruit, have their flesh and their fat all tinged throughout of a violet colour.

JUNIPER, *juniperus*, in *Botany*, a genus of the *discois mundulifolia* class. Its characters are these: it hath male and female flowers on different plants, and sometimes at separate distances on the same plant; the male flowers have a conical calyx; the flowers are placed by threes, opposite each other, and terminated by a single one; the scales are broad, lying on each other, and fixed to the column by a very short foot stalk; the flower has no petal; but three stamina, joined in one body below; the female flowers have a small three-pointed empalemeut, sitting upon the germen; and they have three stiff, acute, permanent petals, and three styles; the germen sitting below the empalemeut, becomes a roundish berry, inclosing three bony seeds, which are oblong, angular on one side, but convex on the other. Miller.

The confusion in names that has arisen from the calling some of the *juniper* by the name of *cedar*, is as old as Theophrastus. In the days of this author the Greeks plainly did not distinguish between the names *juniper* and *cedar*, but applied them indistinctly to the same trees; and all the authors since have more or less given into it. The fruit or berries of the shrub *juniperus*, which is common on heaths in different parts of Europe, is much used in medicine.

These berries, which are first green, and when ripe of a dark purple colour, ripen in the autumn. They are chiefly brought to us from Holland and Italy; and should be chosen fresh, not much shrivelled, and free from mouldiness. The sweetness of these berries appears to reside in the juice, or soft pulpy part; the bitterness in the seeds; and the aromatic flavour in oily vesicles, spread throughout the substance, both of the pulp and of the seeds, and distinguishable even by the eye.

Juniper berries give out nearly all their virtue, both to water and rectified spirit, tinging the former of a brownish yellow, and the latter of a bright orange colour. Distilled with water, they yield a yellowish essential oil, very subtle and pungent, resembling the berries in smell, and in quantity, when the berries have been sufficiently bruised, about one ounce from forty. This oil is a very stimulating diuretic; the decoction inspissated to the consistence of a rob or extract, has a pleasant, balsamic, sweet taste, with a greater or less degree of bitterness. This extract may be used with advantage in cases where the more stimulating preparations would be improper; as in catarrhs, debility of the stomach and intestines, and difficulties of the urinary excretions, in persons of an advanced age. Among the aromatics that have been tried in composition with *juniper berries*, sweet fennel seeds, and caraway seeds, seem the best adapted to improve their flavour. A cordial water is prepared in the shops, by drawing off a gallon of proof-spirit from a pound of the berries, and an ounce and a half of each of the seeds. To this water may be usefully super-added, a proper quantity of the rob. Lewis.

Etmüller had a vast opinion of *juniper berries*: the rob made of the expressed juice of the green berries has been called by many, the *theriac Germanorum*; so much are they esteemed by that nation for their alexipharmic qualities.

They are certainly carminative; but their most remarkable properties are, in scouring the viscera, and particularly the reins and urinary passages, as all things of the turpentine kind do; for which reason they are of great service in aithmas, calculi, the jaundice, colic, the stone of the bladder and kidneys, as also in crustities of the stomach.

The wood of this shrub is also of considerable use in phy-

sic; it strengthens the stomach, expels wind, clears the lungs, provokes the menses, and removes obstructions of the viscera: it is farther said to be sudorific, exphetic, and hysterical. From it they draw a spirit, a tincture, an elixir, extract, and a ratia.

It is said it will last a hundred years without corrupting; the chemists add, that a coal of *juniper*, covered with ashes of the same kind, will keep on fire an entire year.

From a larger species of *juniper*, the gum SANDARACHA is obtained.

JUNK, in *Sea-language*, a name given to any remnants or pieces of old cable, which is usually cut into small portions, for the purpose of making points, mats, caskets, tennis, &c.

JUNO, in the *Heathen Mythology*, a goddess; the daughter of Saturn and Ops; the sister and wife of Jupiter; she is otherwise called Lucina.

Juno, as well as Jupiter, had a great variety of characters among the ancients; but the favourite one of them all, among the Romans, was that of the *Juno Matrona*, dressed like the Roman matrons in a long robe; which covered her from head to foot. The figure of the Roman emperors were often formed under this character of *Juno*. Such is the statue of Seizus, at the Villa Mattei in Rome. This *Juno* was called indifferently, *Juno Matrona* and *Juno Romana*. The *Juno Regina*, and *Juno Moneta*, are always represented on the ancient gems and medals, in a very fine and magnificent dress. We may observe, that Virgil, *Æn. l. v. v. 17. and Æn. l. v. 614.* speaks of *Juno*, not according to the appearance she used to make among the Romans, but according to the representations of her in other countries. In one place, where he describes her arms and military chariot, he speaks of the Carthaginian *Juno*; and in the other, he has given her an angry and warlike figure, which belongs to the *Juno Argiva*, or some particular *Juno* of the Greeks. However, the *Juno Sisyptia* among the Romans, appears on several medals in a war chariot, and with a spear in her hand. There was also a mild *Juno*, as well as mild Jupiter, among the Romans; under which character, her face appeared more gentle and good-humoured than usual; but the most obvious and striking character of *Juno*, which we derive from the writings of Homer and Virgil, is that of an impetuous and haughty wife. These poets often represent her scolding at Jupiter, thus casting him. Nevertheless, she was anciently considered as the great patroness of marriage and a wedded life. *Juno*, under the character of presiding over the air, is represented in a light car, drawn by peacocks, and attended by the *Auræ*, or nymphs of the air. See *JUPITER infer.*

JUNO, in *Astronomy*, a name given by some to the second satellite of Jupiter.

JUNONES. See *GENIUS*.

JUNTA, called also **JUNTO**, and **JUNCTO**, a council, or company, of several persons, meeting for the dispatch of any business.

The term is particularly used in the Spanish and Portuguese affairs.—On the death of Charles II. king of Spain, the kingdom was governed, during the absence of Philip V. by a *junta*.

In Portugal they have three considerable *juntas*; the *junta de commerce*, that of the *three estates*, and that of *taxes*. The first was established by King John IV. this is a council of marine. The same king also assembled the states of his kingdom, to create the tribunal of the *junta* of the three estates. King Peter II. created the *junta* of Tobacco, in 1675; it consists of a president and six counsellors.

IVORY, the tooth, or tusk, of an elephant, growing on each side of his trunk, somewhat in form of a horn. Ivory is much esteemed for its colour, its polish, and the fineness of its grain when wrought. Dioscorides says, that by boiling it the space of six hours with the root of mandragoras, it becomes so soft and tractable, that any one may manage it as he pleases.

In the history of the French Academy, for the years 1742, and 1743, there is an account that M. Geoffroy produced before the academy, a small ivory spoon, which, by lying long in mustard, was become flexible and transparent like horn; that M. Fouchy saw an ivory spoon, which, by lying for a considerable time in milk, was become supple like leather; and that M. Hanauld produced bones which had been softened by steeping in vinegar, afterwards hardened to their natural state by sleeping in water, and softened a second time by vinegar. Dr. Lewis has observed, that the nitrous and marine acids diluted, and the aceticus acid, make bones flexible and tough like leather; but that the diluted vitriolic acid, though it softens them to a considerable degree, makes them at the same time brittle: nor has he found, that the softened bones, whatever acid they were softened by,

recovered

recovered their hardness by sleeping in water. Shells of softened *ivory*, after lying above a month in water, continued nearly as soft as when they were taken out of the acid liquor. *Ivory* may be softened and whitened by boiling red sage leaves in threedistilled white wine vinegar, with a little quicklime, and putting in the *ivory* while the liquor is boiling: *Ivory* may be also whitened and cleaned from spots, by laying it in quicklime, and pouring a little water on it: the quantity of water should be small, lest the heat be too great, and the *ivory* scale and become brittle.

The *ivory* of the file of Ceylon, and that of the island of Achem, have this peculiarity, that they never become yellow, as those of the Terra Firma, and East Indies do; on which account the former are much dearer.

A green dye may be given to *ivory*, by steeping it in aqua fortis, tinged with copper or verdigris, or in two parts of verdigris and one of fil ammoniac, ground well together, with strong white-wine vinegar poured on them. And by converting the aqua fortis into aqua regia, by dissolving a fourth part of its weight of sal ammoniac in it, *ivory* may be stained of a fine purple colour.

Ivory, bone, horn, and other solid parts of animals, may be stained black, in the same manner as *ivory*. These substances may be stained yellow, by boiling them first in a solution of one pound of alum, in two quarts of water; and then, having prepared a tincture of the French berries, by boiling half a pound of the berries, pounded, in a gallon of water, putting them into this tincture, after it has boiled about an hour, and letting them remain there half an hour. Turmeric root may be used instead of the berries; but in this case the *ivory*, &c. must be dipped in alum-water after it is taken out of the tincture. *Ivory*, &c. may be stained blue, by first staining it green, and then dipping it in a solution of pearl-shells made brogue, and boiling hot; or it may be otherwise boiled in the tincture of indigo, prepared by the dyers; and afterwards in a solution of tartar, made by dissolving three ounces of white tartar, or cream of tartar, in a quart of water. For other processes and colours, see DYEING of Bone, &c. *Colouring and Staining of Bone, and Tortoise shell.*

Ivory may be prepared as a ground for MINIATURE painting, by cleaning the *ivory* leaves or tables, and rubbing them over with the juice of garlic. This is said to be more efficient for taking off the greenness, which prevents the colours from sinking on the ground, than soap-gall. *Ivory* has the same medical virtues with hartshorn; its shavings too, like those of hartshorn, boil into a jelly with water, and has the same restorative quality. See HARTSHORN.

IVORY BLACK. See *IVORY BLACK*.

IVORY, Fossil. The abundance of elephants teeth found buried in different parts of the world, and many of those parts such as no elephant is ever known to have lived in, have given great amusement to naturalists. The long tusks, which are what we call *ivory*, are the only teeth the vulgar are acquainted with in this creature; yet even these, in their fossil state, have often been mistaken for horns, or other animal parts. The grinders of this animal are so exceedingly large, and of so singular a shape, that it requires some knowledge in natural history to discover them at sight, and many have mistaken them when imperfect, for parts of a perished shell-fish of the nautilus kind, their root being hollowed all along and armed with an indented ridge on each side, in the manner of the back parts of some shells of that and of the cornu ammonis kind.

We are not to wonder that the teeth of elephants are found more frequently than any other bones of the animal, since their use in the creature required that they should be harder than any other bone, and that hardness has preserved them in places where the other bones have perished. The different state in which these teeth are found, is wholly owing to the different juices abounding in the earth in the place where they were deposited, some of those juices being of power to preserve, others to destroy them; some eating them insensibly away, some as it were calcining them by slow degrees, and others rendering them greatly more hard and durable than before. Mem. Acad. Par. 1727.

Count Macgill, and some other writers, have thought it an easy solution of the question of the teeth and bones of elephants being found in countries where elephants are not naturally found, that we owe them to the Romans, who bringing them over for their use in war, buried them wherever they happened to die. But Sir Hans Sloane expresses himself very justly against this opinion: he observes, that of the remains of elephants found in Europe, nothing is so common as the *ivory* tusks. Now, as he well observes, the Romans held *ivory* in the highest esteem, and it sold among them at a great price; where-

fore had they been the buyers of these elephants, they would certainly have taken away the *ivory* tusks first. It is certain, therefore, that accident, and not design, hath buried these bones, and that accident can have been no other than some prodigious inundation. Woodward is desirous of making the universal deluge to have done all this, but that seems not necessary to be supposed in every case. Sir Hans Sloane gives an enumeration of the most curious of these pieces of fossil *ivory*, which his own cabinet contained, and of some others of the most remarkable, mentioned by authors; from which we may form a very distinct idea both of the nature of the bodies themselves, and of the places where they are usually met with. See Philof. Trans. N° 453. p. 458.

The power of subterraneous calcinations to render things of this kind brittle, is remarked by the same author from Moreton's History of Northamptonshire, in the influence of a fissile tusk of an elephant which was in the whole at least six feet long, and had preserved its natural whiteness, though rendered so brittle as to fall into several pieces in the sifting. This was dug up near Little Bowden, in Northamptonshire, and the strata of the place where it lay, were as follows: 1. Vegetable mould fourteen inches. 2. Loam a foot and half. 3. Large pebbles, with a small mixture of earth among them, two foot and a half. 4. Blue clay; in the upper part of this last stratum, the tooth was found.

Sir Hans mentions another elephant's tusk very entire and found in Siberia. The like are common in Siberia and many parts of Russia, and are so little injured, that they are used as *ivory*, and are supposed to be the teeth of a vast animal called the mammoth, which they think lives under ground. Phil. Trans. N° 468. See farther on this subject, ELEPHANT'S BEAK.

JUPATUMA, in Zoology, a name by which some call a very remarkable American animal, known among us by the name of the opossum.

JUPITER, or **Jove**, in the *Heathen Mythology*, the sovereign god of the heathens; the son of Saturn and Ops; born in the island of Crete, at the same birth with Juno; he married Juno, expelled his father out of his kingdom, and divided the kingdom of the world with his brethren. Under several shapes he is said to have played many wanton pranks; so that according to poetic fiction, he filled heaven with his natural children.

As mankind are directed by an internal spirit or mind, the universe also is governed by an over-ruling intelligence; which as the cause and preserver of all animal beings, was called, *Jus* & *Zeus*. See GOD.

The heathens in general believed that there was but one supreme God; but when they considered this one great being as influencing the affairs of the world, they gave him as many different names; and hence proceeded their variety of nominal gods. When he thundered or lightened, they called him *Jupiter*; when he calmed the sea, Neptune; when he guided their councils, Minerva; and when he gave them strength in battle, Mars. In proof of all these they used different representations of this *Jupiter*, &c. and considered them, vulgarly at least, as so many different persons. They afterwards regarded each of them in different views: e. g. The *Jupiter*, that showered down blessings, was called the *kind Jupiter*; and when punishing, the *terrible Jupiter*. There was also one *Jupiter* for Europe, and another for Africa; and in Europe, there was one great *Jupiter* who was the special protector of the Romans: nay, there was scarce a town or hamlet perhaps, in Italy, that had not a *Jupiter* of its own; and the *Jupiter* of Terracina or *Jupiter Anxur*, represented in medals as young and beardless, with rays round his head, more resembled Apollo than the great *Jupiter* at the Capitol. In this way *Jupiter* at length had temples and different characters almost every where: at Carthage, he was called Ammon; in Egypt, Serapis; at Athens, the great *Jupiter* was the Olympian *Jupiter*; and at Rome, the greatest *Jupiter*, was the Capitoline *Jupiter*, who was the guardian and benefactor of the Romans, and whom they called the best and greatest *Jupiter*; *Jupiter optimus maximus*. The figure of this *Jupiter* was represented in his chief temple on the Capitoline hill, as sitting on a curule chair, with the fulmen or thunder, or rather lightning in one hand, and a scepter in the other. This fulmen in the figures of the old artists was always adapted to the character under which they were to represent *Jupiter*. If his appearance was to be mild and calm, they gave him the conic fulmen or bundle of flames wreathed close together, held down in his hand: When punishing, he holds up the same figure, with two transverse darts of lightning, sometimes with wings added to each side of it, to denote its swiftness: this was called by the poets, the three-forked bolt of Jove: and when he was going to do some

some exemplary execution, they put in his hand a handful of flames, all let loose in their utmost fury; and sometimes filled both his hands with flames. The superiority of *Jupiter* was principally manifested, in that air of majesty which the ancient artists endeavoured to express in his countenance: particular attention was paid to the head of him, the eye-brows and the beard. There are several heads of the mild *Jupiter* on ancient seals; where his face has a mixture of dignity and ease in it, admirably described by Virgil, *Æn.* l. v. 256. The features of the Terrible *Jupiter* were generally of black marble, as those of the former were of white: the one fitting with an air of tranquillity, the other standing, more or less disturbed. The face of the one is pacific and serene; of the other angry or clouded. On the heads of the one the hair is regular and composed; in the other, it is discomposed, that it falls half-way down the forehead. The face of the *Jupiter Tonans* resembles that of the Terrible *Jupiter*: he is represented on gems and medals as holding up the triple bolt in his right hand, and standing in a chariot, which seems to be whirled on impetuously by four horses. Thus he is also described by the poets. Ovid *Deian.* *Herc.* v. 28. Horace *lib. l. od. 34. v. 8.* *Jupiter*, as the intelligence presiding over a single planet, is represented only in a chariot and pair; on all other occasions, if represented in a chariot, he is always drawn by four horses. *Jupiter* is well known as the chief ruler of the air, whose particular province was to direct the rains, the thunders, and the lightning. As the dispenser of rain, he was called *Jupiter Pluvius*; under which character he is exhibited seated in the clouds, holding up his right hand, or extending his arms almost in a straight line each way, and pouring a stream of hail and rain from his right hand on the earth; whilst the fulmen is held down in his left. The wings that are given to him relate to his character of presiding over the air: his hair and beard in the Antique style are all spread down by the rain, which descends in a sheet from him, and falls for the refreshment of the Romans; whilst their enemies are represented, as struck with the lightning and lying dead at their feet. Spence's *Polymet.* p. 46, 182, and 210, &c.

JUPITER'S beard, barba Jovis, the name given to a species of anthell.

See *LADY'S FINGER*.

AMERICAN JUPITER'S head, is a species of *AMORPHA*.

JUPITER'S Diadem, is a species of *JULIA* or *LAGER*.

JUPITER Fulminans and Fulgurator. See *FULMINANT*.

JUPITER, Flamen of. See *FLAMEN* and *DIALIS*.

JUPITER, 4, in *Astronomy*, one of the superior planets, remarkable for its brightness; and which, by its proper motion, seems to revolve round the earth in about twelve years. See *PLANET*.

Jupiter is situate between Saturn and Mars: it has a rotation round its own axis in 9 hours 56 minutes; and a periodical revolution round the earth in 4332 days, 12 hours, 20' 9".

Jupiter is the biggest of all the planets: its diameter to that of the sun appears, by astronomical observations, to be as 1056 to 100000; to that of Saturn, as 1056 to 8764; to that of the earth, as 1056 to 80. For the comparative gravities at the surface, densities, quantities of matter, &c. of the Sun, *Jupiter*, Saturn, and the Earth: See *PLANETS*. For the apparent diameter, see *DIAMETER*.

The mean distance of *Jupiter* from the sun, is 5201 of those parts whereof the mean distance of the earth from the sun is 1000, though Kepler only makes it 5196 of those parts. See *DISTANCE*.

M. Cassini calculates *Jupiter's* mean distance from the earth to be 115000 semidiameters of the earth.—Gregory compares the distance of *Jupiter* from the sun to be above five times as great as that of the earth from the sun; whence he gathers, that the diameter of the sun, to an eye placed in *Jupiter*, would not be a fifth part of what it appears to us; and, therefore, his disk would be twenty-five times less, and his light and heat in the same proportion. In reality, the sun appears but 1/5th to big to *Jupiter* as to us, and his light and heat are in the same small proportion, but compensated by the quick returns thereof, and by four moons revolving round him. The true distance by the latest observations is 494,990,976 miles. See *PLANETS*.

The inclination of *Jupiter's* orbit, that is, the angle, formed by the plane of its orbit, with the plane of the ecliptic, is 1 deg. 20 min. The place of its aphelion ϕ , 9° 10' and the place of its ascending node ω 7° 29'. For the eccentricity of *Jupiter's* orbit, see *EXCENTRICITY*.

Jupiter is one of the superior planets, that is, of those which are above the sun: hence it has no parallax; its distance from the earth being too great to have any sensible proportion to the diameter of the earth. See *PARALLAX*.

Though it be the greatest of the planets, yet its revolution about its axis is the swiftest. Its polar axis is oblique to be shorter than its equatorial diameter; and Sir Isaac Newton computes the difference to be as 3 to 9. So that its figure is a spheroid; and the swiftness of its rotation occasions this spheroidism to be more sensible than that of any other of the planets.

Jupiter appears almost as large as Venus; but he is not altogether so bright: he is eclipsed by the moon, by the sun, and even by Mars.—Herschel is said to have once observed *Jupiter's* diameter seven inches, having inequalities like the moon.

Jupiter has three appendages, called *zans*, or *Ides*, which Sir Isaac Newton thinks are formed in his atmosphere.—In the first and second *zans*, or spots, from whose motion, the motion of *Jupiter* round its axis is said to have been first determined: the discovery of which is controverted between Laflamme, P. Goignies, Cassini, and Campani.

The four little stars, or moons, which move round *Jupiter*, were first observed by Galileo, who called them the *stellæ Medicæ*; but we call them the *Jovianæ* of *Jupiter*. For the periods, distances, &c. of these satellites, see *SATELLITES*.

These four moons make an extremely pleasing spectacle to the inhabitants of *Jupiter*: for sometimes they rise altogether; sometimes they are all together in the meridian, ranged one behind another; and sometimes all appear in the horizon. And, that they frequently undergo eclipses, the distances whereof are found of especial use in determining the longitude. Cassini has made tables for calculating the conjunctions, and eclipses, of *Jupiter's* first satellite. See *PERIODS* &c.

Comparative Astronomy, *lib. 1. c. 12.*—The day and night are of the same length in *Jupiter* all over his surface; viz. five hours each; and even of his diurnal rotation being nearly at right angles to the plane of his annual orbit.

And this is a great advantage and wisely ordered by the Author of nature. For the axis of this planet were inclined by any considerable number of degrees, just as many degrees more or less would in their turn be almost six of our years less or more. And, as each degree of a great circle in *Jupiter* contains four hundred and six of our miles, at a mean rate, it is easy to judge what vast tracts of land would be rendered uninhabited by any considerable inclination of his axis. Though there be four planets, planets below *Jupiter*, yet an eye placed on his surface could never perceive any of them; unless, perhaps, as being passing over the sun's disk, when they happen to come between the eye and the sun.—The parallax of the sun, viewed from *Jupiter*, will scarce be sensible, so more than that of Saturn, neither being much above 20 seconds; so that the sun's apparent diameter in *Jupiter* will not be above six minutes. The circumference of *Jupiter's* satellites will appear almost as big as the moon does to us; viz. five times the diameter, and 15 times the disk of the sun.—Dr. Gregory adds, that an observer in *Jupiter* would easily distinguish two kinds of planets, four nearer him; viz. the satellites and two, viz. the sun, and Saturn; more remote. The former, however, will fall vastly short of the sun in brightness, notwithstanding the great disproportion in the distances and apparent magnitude. From these four distinct moons the inhabitants of *Jupiter* will have four different kinds of months; and the numbers of months in that year will not be less than 4500. These moons are eclipsed so often as, being in opposition to the sun, they fall within the shadow of *Jupiter*; and again, as, when being in conjunction with the sun, they project their shadows to *Jupiter*, they make an eclipse of the sun in an eye placed in that part of *Jupiter* where the shadow falls. But in regard the orbits of these satellites are in a plane which is inclined to, or makes an angle with *Jupiter's* orbit, their eclipses become central, when the sun is in one of the nodes of these satellites; and when out of this position, the eclipses may be total, though not central, because the breadth of *Jupiter's* shadow is nearly decuple to that of the breadth of any of the satellites; and the apparent diameter of any of these moons is nearly quintuple the apparent diameter of the sun. It is owing to this remarkable largeness of diameters, and the small inclination the plane of the orbits of the satellites has to the plane of *Jupiter's* orbit, that in each revolution there happens eclipses both of the satellites, and of the sun; though the last be of a considerable distance from the nodes. Farther, the inferior among these satellites, even when the least of its greatest distance from the nodes, will occasionally eclipse and be eclipsed by the sun to an inhabitant of *Jupiter*; though the remotest of them, in this case, drops falling into *Jupiter's* shadow, and *Jupiter* into his, fall two years together. To this it may be added, that one of these satellites sometimes eclipses

eclipses together; where the phases must be different, may frequently oppose to that of the satellite falling into the shadow of Jupiter just mentioned; for in this the eastern limb immerses first, and the western emerges last; but in the others it is just the reverse.

The shadow of Jupiter, though it reaches far beyond its satellites, yet falls much short of any other planet. Indeed, Jupiter's shadow could not reach Saturn, the next superior planet, unless Jupiter's diameter were half that of the sun; whereas, in effect, it is not one ninth of it.

The courses of Jupiter's satellites, and their various eclipses, would render navigation very safe and easy on the globe of Jupiter. Even we, at this distance, can make very good use of them; those eclipses being found one of our best means for determining the LONGITUDE at sea.

JUPITER, among *Athenians*, signifies the philosophers gold.

The gentlemen of this profession apply every thing to their art, which the mythologists mention of the god Jupiter, pretending that the ancient fables are to be understood in a figurative sense; for instance, Jupiter is the matter of the gods and gold, say they, is the most precious of metals. Mercury is the embassador of Jupiter; and this shows with how much ease Mercury insinuates into every thing. Jupiter holds the thunderbolt as his sceptre; which evidently points out the external fulgurat used in projection. Jupiter has the heavens for his ordinary habitation; that shows him volatile, dry, and hot. The debauches of Jupiter, who sought for pleasure in the low, but profligate and fruitless earth, discover, say they, its fecundity, and that gold might be made, were but the way of preparing it discovered. In a word, Jupiter is the son of Saturn, which bears some resemblance between the qualities of gold and lead.

JUPITER, in *Chemistry*, denotes TIN.

JUPUJUBA, the Brazilian name of a kind of the woodpecker kind, more commonly known by the name JAYU.

JUQUER. This plant is found in Brazil, and is of a poisonous nature; but if we may credit Piso, its root is its antidote.

JURATAM—*Affixio eadem in juramentum*. See *AVISA*.

JURATI. See *JURATO*.

JURATIS, *Non parum in*. See *NON PARUM*.

JURATORES, *whisperers*. See *DIATRINGAS*.

JURATS, JURATI, magistrates in the nature of ALDERMEN, for the government of several corporations.

Thus we meet with the mayor and jurats of Maidstone, Rye, Winchester, &c.—So also Jersey has a bailiff and twelve jurats, or sworn assistants, to govern the island.

JURE.—*De JURE*. See *DE FIDE ET POSSESSIONE*.

JURE, *Qua*. See *QUO JURE*.

JURIDICI *dicti*. See *DICI*.

JURIS UTRUM, in *Law*, a writ called the parson's writ of right, which lies for the parson of a church, or prebendary, at common law, and for a vicar by stat. Ed. III. c. 17, whose predecessor hath alienated the lands and tenements thereof, by which they may recover lands and tenements belonging to the church, or of which they were dispossessed; or which were recovered against them by verdict, confession, or default, without praying in aid of the patron and ordinary; or on which any person has intruded since the predecessor's death. But since the restraining statute of 13 Eliz. c. 10, whereby the alienation of the predecessor, or a recovery suffered by him of the lands of the church, is declared to be absolutely void, this remedy is of little use, unless where the parson himself has been deforced for more than twenty years; for the succession, at any competent time after his accession to the benefice, may enter, or bring an ejectment.

JURISCONSULTUS, or JURISCONSULTUS, in *Law*, among the Romans, was a person learned in the law; a master of the Roman jurisprudence; who was consulted on the interpretation of the laws, and customs, and the difficult points in law-suits.

The fifteen books of the *DIGEST* were compiled wholly from the answers, or reports, of the ancient *jurisconsulti*. Trebonianus, in describing the two thousand volumes from whence the *CODE* and *DIGEST* were taken, has deprived the public of many things, which would have given them light into the office of the ancient *jurisconsulti*.

We should scarce have known any thing beyond their bare names, had not Pomponius, who lived in the second century, taken care to preserve some circumstances of their office.

The Roman *jurisconsulti* seem to have been the same with our chamber-counsellors, who arrived at the honour of being consulted, through age and experience, but never pleaded at the bar. Their pleading advocates or lawyers, never became *jurisconsulti*.

In the times of the commonwealth, the *advocati* had by much the more honourable employment, as being in the

ready way to attain to the highest preferments. They then despised the *jurisconsulti*, calling them in derision *foreriders*; and *legibus*, having invented certain forms, and maxims, in order to give their answers the greater appearance of gravity and mystery. But in process of time they became so much esteemed, that they were called *prudentes* and *legisprudentes*, and the emperors appointed the judges to follow their advice. Augustus at length advanced them to be public officers of the empire; so that they were no longer confined to the petty counsels of private persons.

Bern. Rutilius has written the lives of the most famous *jurisconsulti*, who have lived within these two thousand years.

JURISDICTION, a power, or authority, which a man has to do justice in cases of complaint made before him. There are two kinds of jurisdiction, the one *ecclesiastical*, the other *secular*.

JURISDICTION, *secular*, belongs to the king, and his justices, or delegates.

The courts and judges at Westminster have jurisdiction all over England, and are not restrained to any county or place; but all other courts are confined to their particular jurisdictions, which if they exceed, whatever they do is erroneous. There are three sorts of inferior jurisdictions: the first is *tenure placita*, to hold pleas, and the plaintiff may sue either there or in the king's courts. Another is the consue of pleas, where a right is involved in the lord of the franchise to hold pleas; and he is the only person that can take advantage of it, by claiming his franchise. The third sort is an exempt jurisdiction, as where the king grants to some city, that the inhabitants shall be sued within their city, and not elsewhere; though there is no jurisdiction that can withstand a *certiorari* to the superior courts. See *JUSTICE*, and *COURT*.

Ecclesiastical JURISDICTION belongs to bishops and their deputies. See *BISHOP*, and *OFFICIAL*.

Bishops, &c. have two kinds of jurisdiction; the one *internal*, which is exercised over the conscience in things purely spiritual; and this they are supposed to hold immediately of God.

The other is *external*, which is a privilege some princes have given them in terminating disputes between ecclesiasticals and laymen. See *CONVENTIONS*.

JURISPRUDENCE, the science of what is just and unjust, or of the laws, rights, customs, statutes, &c. necessary for the doing of justice.

Civil jurisprudence is that of the Roman law; *canonical*, that of the canon law; and *feudal*, that of fees.

JURON, JURATOR, in a *Legal Sense*, is one of those twenty-four, or twelve men, who are sworn to deliver truth upon such evidence as shall be given them touching any matter in question.

The punishment of jury jurors attainted of giving a verdict contrary to evidence, willingly, is very severe. See *ATTAINT*.

JURORI, *Challenge to the*. See *CHALLENGE*.

JURUCUA, in *Zoology*, the Brazilian name of a species of tortoise. This has feet almost in the shape of wings, the fore ones about six inches long, the hinder ones considerably shorter; its tail is short, and of a conic figure; its eyes large and black; its mouth has no teeth, but resembles the beak of a bird. It frequently grows to four feet long, and about three in width; its ribs are fastened to the shell, and are eight on each side; the middle ones of these are the longest, the fore and hinder ones being the shorter. The flesh and eggs of this species are very delicately tasted; they lay their eggs in holes on the sea-shore, covering them over with sand, and leaving them for the sun to hatch them. There are usually a great many very odd figures, like geometrical lines, running in various directions on the shell; the whole ground of the shell is usually black and very glossy, adorned with yellow variegation; but this is no certain character of the species, the varieties in the colouring of these shells being very great.

JURUCAPEBA, in *Ichthyology*, the name of a sea-fish, of the tunny or wraite kind, caught about the shores of the Brazils, and called also *itana*. It is usually about five or six inches long, and about a third part of its length in breadth; its mouth is extremely large and wide, and of a somewhat triangular figure.

It is caught among the rocks, and is a very delicate fish for the table.

JURURA, in *Zoology*, the name of a species of tortoise, common in the Brazils. It is a small kind, seldom exceeding ten fingers in breadth, and eight or nine in length, and is of an elliptic figure; its under shell is about nine fingers long, and four and a half broad, and is flat; it can at pleasure hide its whole body in the shell, or thrust out its neck to three fingers breadth distance; the head is thick and long, the nose elevated and pointed; the mouth is large, and the eyes black; it

has four long claws on its feet; its tail is short and pointed; and its skin is rough and scaly. The upper shell is brown, the lower yellow; its eggs are white and round, and about half the size of a hen's egg, and are very well tasted.

JURY, in *Common Law*, signifies twenty-four, or twelve men, sworn to inquire of a matter of fact, and declare the truth, upon such evidence as shall be delivered them touching the matter in question.

The mode of trial by jury is very ancient, and seems to have been coeval with the civil government of this nation. Traces of juries may be found in the laws of all those nations, which adopted the feudal system, as in Germany, France, and Italy; and in England we find actual mention of them so early as the laws of king Ethelred, and even then not as a new invention. The establishment and use of this mode of trial in our island, though for a time greatly impaired and shaken by the introduction of the Norman trial by battle, were so highly esteemed and valued by the people, that no conquest, no change of government, could ever prevail to abolish it. See *JUDICIUM peritum*.

Trials by jury in civil causes are of two kinds; extraordinary and ordinary. The first species of extraordinary trial by jury is that of the grand assize. See *ASSIZES*.

Another species of extraordinary juries is the jury to try an *ATTAIN*.

With regard to the ordinary trial by jury in civil cases, when an issue is joined, the court awards a writ of *venue facias*, which is accordingly issued to the sheriff. Thus the cause stands for a trial at the bar of the court itself, provided it be of consequence; but all trifling suits are ended in the court below, hundred, or county courts. However, when the assize began to bring actions of any trifling value in the courts of Westminster-hall, it was found very inconvenient to compel the parties, witnesses, and jurors, to come from the remotest parts of the country to try a trivial action at Westminster; and, therefore, the legislature referred matters in issue to the *JUSTICES of assize*. Accordingly it was enacted by 13 Edw. I. cap. 30. that a clause of *assize prius* should be inserted in all the writs of *venue facias*, by virtue of which the sheriff returned his jurors to the court of the justices of assize, which was sure to be held in the vacation before Easter and Michaelmas terms, and there the trial was held. But this method was inconvenient, and, therefore, was altered by 42 Edw. III. cap. 11. which statute enacted, that no inquest, except of assize and gaol delivery, should be taken by writ of *assize prius*, till after the sheriff had returned the names of the jurors to the courts above. It is now the course to make the sheriff's *venue returnable* on the last return of the same term, wherein issue is joined, viz. Hilary or Trinity terms, which are called *issuable terms*; and he returns the names of the jurors in a panel, i. e. little pane, or oblong piece of parchment, annexed to the writ. This jury is not summoned, and, therefore, not appearing at the day, must unavoidably make default: for which reason a compulsive process is now awarded against the jurors, called in the common pleas a writ of *habeas corpus juratorum*, and in the king's bench a *RETURN DECEAS*. The jury, therefore, on the roll or record is, that the jury is required, through defect of the jurors, till the first day of the next term, then to appear at Westminster; unless before that time, viz. on Wednesday the fourth of March, the justices of our lord the king appointed to take assizes in that county shall have come to the place assigned for holding the assize, &c. And as the judges are sure to come and open the circuit commissions on the day mentioned in the writ, the sheriff returns and summons this jury to appear at the assize, and there the trial is had before the justices of assize and *assize prius*; among whom are usually two of the judges of the courts at Westminster, the whole kingdom being divided into six *CIRCUITS* for this purpose. If the *SHERIFF* be not an indifferent person, or if he be a party in the suit, or be related either by blood or affinity to either of the parties, the *venue* shall be directed, not to him, but to the *CORONER*; and if any exception lies against them, to two clerks of the court, or to two persons named by the court and sworn, and called *assizes*, or electors, who shall indifferently name the jury, and their return is final. In order farther to remove all suspicion of partiality, it is provided by the statutes 4 Edw. III. cap. 2. 8 Ric. II. cap. 2. and 35 Hen. VIII. cap. 24. that no judge of assize should hold pleas in any county where he was born or inhabits.

When the general day of trials is fixed, the plaintiff, or his attorney, must bring down the record to the assizes, and enter it with the proper officer, in order to its being called in court. If it be not so entered, it cannot be tried; therefore it is in the plaintiff's breast to delay any

trial by not carrying down the assize, unless the defendant undertakes to bring in the trial by giving proper notice to the plaintiff. This proceeding is called the trial by *PROVISO*. However, this practice begins to be disused, since the statute 14 Geo. II. cap. 12. which enacts, that if, after issue joined, the assize is not carried down to be tried according to the course of the court, the plaintiff shall be esteemed to be non-assize, and judgment shall be given as in a case of *non-assize*. In case the plaintiff intends to try the cause, he is bound to give the defendant (if he lives within forty miles of London) eight days notice of trial; and if he lives at a greater distance, fourteen days notice; and if he changes his mind, and does not countermand the notice fix a day before the trial, he shall be liable to pay costs to the defendant for not proceeding to trial, by the last mentioned statute. The defendant, however, or plaintiff, may, upon good cause shown to the court above, in open absence or sickness of a material witness, obtain leave upon motion to defer the trial of the cause till the next assize. But when the cause is called on regularly in court, the record is conveyed to the judge, while the jury is called and sworn. To this end the sheriff returns his compulsive process, the writ of *habeas corpus*, or *assize prius*, with the panel of jurors annexed, to the judge's clerk at court. The jurors contained in the panel are either special or common jurors.

See *Special Jurors*. A common jury is ordered by the sheriff, according to the directions of the statute 18 R. II. cap. 25. which appoints, that the sheriff shall return a separate panel for every separate cause, as in tenancy, but one and the same panel for every cause in action at the same assizes, containing not less than thirty names, nor more than seventy-two jurors; and that these persons, being written on tickets, shall be put into a box or cask; and when each cause is called, twelve of these persons, whose names shall be first drawn out of the box, shall be sworn upon the jury, unless absent, called away, or excused; and unless a previous view of the land in question, or other matters in question, shall have been thought necessary by the court; in which case six or more of the jurors returned, to be agreed on by the court, or named by a judge, or other proper officer of the court, shall be appointed to take such a view; and then such of the jury as have appeared upon the view, shall be sworn on the inquest, previous to any other jury.

List of jurors qualified according to the acts 4 & 5 W. & M. cap. 24. 7 & 8 W. III. cap. 22. and 3 & 4 Ann. cap. 12. are now to be made from the rates of each parish. The justices at Michaelmas sessions are to issue warrants to the high constables, who require the petty constables to prepare such lists; and if the high constables neglect to issue their warrants for this purpose, they shall forfeit 10*l*. These lists are to be taken on the doors of churches, &c. twenty days before Michaelmas, that public notice may be given at persons omitted who are qualified, and of persons omitted, who ought to be omitted. 3 Geo. II. cap. 25. And if any persons are inserted wrongfully, or omitted for the sake of reward, &c. the petty constable incurs a forfeiture of 20*l*. The lists shall be delivered by the high constables, at Michaelmas sessions, in open court, or when they are falsified by them, and sworn on oath, and also signed by the justice, they shall be delivered by the petty constables to the high constables, who shall deliver them, upon oath, in open court. The constable failing to make such return, shall forfeit 5*l*. Persons who qualify may be discharged by the justices at the roll of the assize. If they shall be forfeited in a book by the rate of the peace, on forfeiture of 2*l*. and duplicate of the same shall, during the sessions, or within ten days after, be delivered by him to the sheriff, who shall make the same, with their additions, &c. to be entered in a book of his own; and if the sheriff shall return any person whose name is not in the duplicate, he is liable to a fine not exceeding 10*l*. nor less than 40*l*. 3 Geo. II. cap. 25. Every summons of jurors shall be made by the sheriff, his officer, or lawful deputy, six days before the assize at least, in Wales eight days before, and in the counties palatine fourteen days before; and the penalty of neglect, or of executing any person for favour or reward, &c. 10*l*. by 7 & 8 W. cap. 32. or a fine of 10*l*. or under imposed by the judge of assize. 3 Geo. II. cap. 25. No person shall be summoned, who has served within one year before in the county of Rutland, or two years before in any other county, not being a county of a city or town, and except the counties of York and Middlesex, under a fine not exceeding 5*l*. Every person who has served, shall have a certificate gratis, testifying his attendance. 3 Geo. II. cap. 25. In the county of York, jurors shall not be returned above once in three years; and the sheriff neglecting his duty shall forfeit 100*l*. and for not discharging a juror,

juror, who has served within four years, and giving notice to the party summoned six days before the assizes or session, shall forfeit 20*l.* to the party with full costs. 7 & 8 W. cap. 31. 3 & 4 Ann. cap. 18. & 10 Ann. cap. 14. In the county of Middlesex, no person shall be returnable to serve as a juror, as any fellow of any *guild*, who hath been returned in the two terms or vacations next before, on pain of the sheriff being fined by the judge 5*l.* or under. 4 Geo. II. cap. 7. And by 7 & 8 W. cap. 32. the inhabitants of the city and liberty of Westminster shall be exempted from serving on any *jury* at the assizes for Middlesex, by reason of their attendance at the courts of Westminster. By the common law, jurors returned, and not appearing, shall lose and forfeit the issues returned upon them. And if a jurymen be called, and, being present, refuse to appear; or having appeared, withdraw before he be sworn, the court may fine him at their discretion. 35 Hen. VIII. cap. 6. And by 20 Geo. II. cap. 19, a juror not appearing and serving in any court of record within the city of London, or in any other city or town corporate, liberty, or franchise, after being openly called three times, &c. shall, without reasonable excuse, be fined not more than 40*l.* nor less than 20*l.* And by 1 Geo. II. cap. 25. in causes of *assumpsit*, every person whose name shall be drawn, and who shall not appear, without reasonable excuse, shall forfeit, not exceeding 5*l.* nor less than 40*l.* If a juror take a bribe of either party, he shall forfeit ten times as much as he hath taken. 1 Ed. III. cap. 10. 34 Ed. III. cap. 8. 38 Ed. III. stat. 1. cap. 12. If a man assault or threaten a juror for giving a verdict against him, he is punishable by fine, imprisonment; and if he strike him in the court, in the presence of a judge of assize, he shall lose his land and his goods, and profits of his lands during life, and suffer perpetual imprisonment. The *jury* is to be chosen of the same class or rank with the parties, and, by the policy of the ancient law, the *jury* was to come *de vicinis*, from the neighbourhood of the village or place where the cause of action was laid in the declaration, and for want of this, the array might be challenged for defect of hundreders. However, this practice was entirely abolished by 4 & 5 Ann. cap. 16. upon all civil actions, except upon penal statutes; and upon those also by the 24 Geo. II. cap. 18. the *jury* being now only to come, *de respectabilibus*, from the body of the county at large, and not *de vicinis*, or from the particular neighbourhood. It is also enacted by 28 Edw. III. cap. 18. that where either party is an alien born, the *jury* shall be one half aliens, and the other denizens, if required, for the more impartial trial. But where both parties are aliens, the whole *jury* are directed to be denizens, by 21 Hen. VI. cap. 4. For other grounds of challenge and qualification of jurors, see CHALLENGE. Jurors in London and Westminster must not only be housekeepers, but have land or goods worth one hundred pounds; and they may be examined on oath as to that point. 3 Geo. II. cap. 25. All cities, boroughs, and corporate towns, are excepted out of the act that settles the qualification of jurors for county assizes or sessions; and trials of felons in corporations may be by men worth 40*l.* in goods, though they have no freehold. Jurors in the term shall have 20*l.* a year freehold, or 20*l.* *l.* copyhold. Any person whatsoever is capable of being put upon the *jury* in a court-decree, and upon the coroner's *jury*. Persons excused from serving on *juries* are those that are sick and decrepit, those not communicant in the country, and men above seventy years old, by 13 Edw. I. cap. 38. and by 7 & 8 Wills III. cap. 32. infants under twenty-one. This exemption is also extended by divers statutes, customs, and charters, to physicians, and other medical persons, counsel, attorneys, officers of the courts, and the like, all of whom, if impeached, must show their special exemptions. Dissenting teachers, qualified under the toleration act, are exempted, and also quakers. Clergymen are also usually excused; but if they are seised of lands and tithes, they are strictly liable to be impeached in respect of their lay fees, unless they be in the service of the king, or of some bishop. If by means of challenge, or other cause, a sufficient number of unexceptionable jurors doth not appear at the trial, either party may pray a *TALE*. When the legal number of twelve is obtained, they are then separately sworn, well and truly to try the issue between the parties, and a true verdict to give, according to the evidence; and hence they are denominated the *jury*, *jurata*, and jurors, *scilicet juratores*. Pleadings are then opened to them by counsel on that side which holds the affirmative of the question in issue: the nature of the case, and the evidence intended to be produced, are next laid before them by counsel also on the same side, and when their evidence is gone through, the advocate on the other side opens the adverse case, and supports it by evidence; and then

the party which began is heard by way of reply. See EXAMINER.

As to such evidence as the *jury* may have in their own conscience, by their private knowledge of facts, it was an ancient doctrine, that this had as much right to sway their judgment as the written or parole evidence which is delivered in court; and, therefore, it hath been often held, that though no proofs be produced on either side, yet the *jury* might bring in a verdict. But this doctrine was gradually exploded, when *ATTAINERS* began to be disused, and new trials introduced in their stead. And if a juror knows any thing of the matter in issue, he may be sworn as a witness, and give his evidence publicly in court. When the evidence on both sides is gone through, the judge in the presence of the parties, the counsel, and all others, sums up, the whole to the *jury*; who, unless the case be very clear, withdraw from the bar to consider of their verdict; and, in order to avoid intemperance and causeless delay, they are to be kept without meat, drink, fire, or candle, unless by permission of the judge, till they are all unanimously agreed. And if they eat or drink, or have any eatables about them, without consent of the court, and before verdict, it is fineable; and if they do so at his charge for whom they afterwards find, it will set aside the verdict. Also, if they speak with either of the parties or their agents, after they are gone from the bar, or if they receive any fresh evidence in private, or, if to prevent disputes, they call lots for whom they shall find, any of these circumstances will entirely vitiate the verdict. And it has been held, that if the *jury* do not agree in their verdict before the judges are about to leave the town, though they are not to be threatened or imprisoned, the judges are not bound to wait for them, but may carry them round the circuit from town to town in a cage. When they are all unanimously agreed, the *jury* return back to the bar; and before they deliver their verdict, the plaintiff is bound to appear in court, by himself, attorney, or counsel, in order to answer the AMERCEMENT, to which by the old law he is liable, in case he fails in his suit, as a punishment for his false claim; a form which is still continued, though the amercement is disused; and if the plaintiff does not appear, no verdict can be given, but the plaintiff is said to be *non-juit*. But in case the plaintiff appears, the *jury* by their foreman deliver in their verdict. When the *jury* have delivered in their verdict, and it is recorded in court, they are then discharged. Such is the process of trial by *jury* in civil cases.

In criminal cases, it is provided by the equity and lenity of the English laws, that no man should be called to answer for any capital crime, unless upon the preparatory accusation of twelve or more of his fellow-subjects, called the grand *jury*. This *jury* considers all bills of INDICTMENT against criminals preferred to the court, which they either approve or find, by writing upon them *Billas vera*, or disallow, by indorsing *IGNORAMUS*, and generally counsils of gentlemen that are freeholders of superior quality to those who form the *petit jury*, who try the prisoners indicted by the other *jury*, and convict them by verdict.

When a prisoner is on his arraignment, has pleaded not guilty, and for his trial hath put himself upon the country, which country the *jury* are, the sheriff of the county must return a panel of jurors that are freeholders, without just exception, and of the *vicus*, or neighbourhood, i. e. of the country where the fact is committed. If the proceedings are before the court of king's bench, there is a time allowed, between the arraignment and the trial, for a *jury* to be impanelled by a writ of *VENIRE FACIAS* to the sheriff, as in civil causes; and the trial in case of a misdemeanour is had at *NISSI PRIUS*, unless it be of such consequence as to merit a trial at bar; which is always invariably had, when the prisoner is tried for any capital offence. But, before commissioners of *oyer & terminer*, and gaol delivery, the sheriff, by virtue of a general precept, directed to him beforehand, returns to the court a panel of forty-eight jurors, to try all felons that may be called upon their trial at that session; and, therefore, it is usual to try all felons immediately, or soon after their arraignment. But persons indicted of smaller misdemeanours, usually give security to the court to appear, for trial at the next assizes or session. See INDICTMENT. When the trial is called on, the jurors are to be sworn, as they appear to the number of twelve, unless they are challenged by the party. See CHALLENGE, & *supra*. *Tales* may be swarded at in civil causes, till the number of twelve is sworn, "well and truly to try, and true do," "liverance make, between our sovereign lord the king, and the prisoner whom they have in charge; and a true verdict to give, according to their evidence." When the *jury* is sworn, if it be a cause of any consequence, the indictment is usually opened, and the evidence

man against another. Though the *justi* were usually made in tournaments, after a general encounter of all the cavaliers, yet they were sometimes singly, and independent of any tournament.

He who appeared for the first time at a *just*, forfeited his helm, or casque, unless he had forfeited before at a tournament.

Just appoi. See APPOI.

JUSTICE, *justitia*, a constant desire, or inclination, to give every one his due; or a habit by which the mind is disposed and determined to give every man his own. *Justice* may be divided into *distributive*, *commutative*, and *legal*.

JUSTICE, *distributive*, is concerned in matters of government, and of beneficence; and is either remuneratory, or punitive: it observes an equality in dealing rewards and punishment, according to each man's condition and merit; for as actions are either good or evil, for the good, rewards must be assigned; and for the evil, punishments; and hence a geometrical proportion is observed.

JUSTICE, *commutative*, is conversant in matters of commerce, and in the equal commutation, or changing, of things; and proceeds according to arithmetical equality, without any regard to persons and circumstances.

JUSTICE, *legal*, is that which resides in the state, or monarch, by whose power and authority the effects of *commutative* and *distributive justice* are frequently superseded, or suspended; as in a dearth of corn, if a person has a flock by him will not sell it, it shall be taken from him; and the like.

JUSTICE, *hand of*. See HAND.

JUSTICE, *officers of*. See OFFICERS.

JUSTICE, *partial*. See PARTIAL.

JUSTITIAN, *temperamentum*, see TEMPERAMENTUM.

JUSTICE, *justitarius*, is likewise an officer appointed by the king or commonwealth to do right by way of judgment.

He is called *justus*, not *judge*; anciently *justitia*, not *justitarius*, because he has his authority by deputation, as delegate to the king, and not *jura magistratus*; so that he cannot dispute any other in his stead, the *justice* of the forest only excepted.

Of these *justices* we have various kinds in England; viz. *Chief Justice of the king's bench*, is the capital *justice* of Great Britain, and is a lord by his office. His business is chiefly to hear and determine all pleas of the crown; that is, such as concern offences against the crown, dignity, and peace of the king; as treasons, felonies, &c.

This officer was formerly not only *chief justice*, but also chief baron for the exchequer, and master of the court of wards. He usually sits in the king's palace, and there executed that office, formerly performed *per eundem palatium*; he determined in that place all the differences happening between the barons and other great men.

He had the prerogative of being viceregent of the kingdom, whenever the king went beyond sea, and was usually chosen to that office out of the prime nobility; but his power was reduced by king Richard I. and king Edward I. His office is now divided, and his title changed from *capitani iusticie justitarius*, to *capitani justitarius ad placita, etiam regie tenencia, et capitani justitarius hanc regis*. See COURT of king's bench.

Chief Justice of the common pleas, he who, with his assistants, hears and determines all causes at the common law; that is to say, all civil causes, between common persons, as well personal as real; and he is also a lord by his office.

JUSTICE of the forest, is a lord by his office, who has power and authority to determine offences committed in the king's forests, &c. which are not to be determined by any other court, or *justice*.

Of these there are two, whereof one has jurisdiction over all the forests on this side Trent, and the other beyond it.

By many ancient records, it appears to be a place of great honour and authority, and is never bestowed but on some person of great distinction. The court where this *justice* sits is called the *justice seat of the forest*, held once every three years, for hearing and determining all trespasses within the forest, and all claims of franchises, liberties, and privileges, and all pleas. It causes whatsoever therein arising. This court may fine and imprison for offences within the forest, it being a court of record; and therefore a writ of error lies from hence to the court of king's bench. The last court of *justice seat of any forest* was then held in the reign of Charles I. before the earl of Holland. After the Restoration another was held, for some time, before the earl of Oxford; but since the Revolution in 1688, the forest laws have fallen into total disuse, to the great advantage of the subject.

• Vol. II. N^o 191.

This is the only *justice* who may appoint a deputy; he is also called *justice in eyre of the forest*.

JUSTICES of assize were such as were wont, by special commission, to be sent into this or that county, to take assizes, for the ease of the subjects.

For, whereas these assizes pass always by jury, so many men might not, without great damage and charge, be brought up to London; and therefore *justices*, for this purpose, by commissions particularly authorized, were sent down to them.

These continue to pass the circuit, by two and two, twice every year, through all England, except the four northern counties, where they go only once, discharging their several businesses by several commissions; for they have one commission to take assizes, another to deliver gaols, and another of oyer and terminer. In London and Middlesex a court of general goal-delivery is held eight times in the year.

All the *JUSTICES of peace* of any county wherein the assizes are held, are bound by law to attend them, or else are liable to a fine; in order to return recognizances, &c. and to assist the judges in such matters as lie within their knowledge and jurisdiction, and in which some of them have been probably concerned, by way of previous examination. See ASSIZES and JURY.

JUSTICES in eyre, *justitarius itinerantis*, or *itrantes*, were those who were anciently sent with commission into divers counties, to hear such causes, especially as were termed *pleas of the eyre*; and that for the ease of the subjects, who must else have been hurried to the courts of Westminster, if the cause were too high for the county courts.

According to some, these *justices* were sent once in seven years, but others will have them to have been sent oftener. Camden says, they were instituted in the reign of king Henry II. A. D. 1184; but they appear to be of an older date.

They were somewhat like our *justices* of assize at this day; though for authority, and manner of proceeding, very different.

JUSTICES of goal-delivery, those commissioned to hear and determine causes appertaining to such as for any offence are cast into prison.

Justices of goal-delivery are empowered by the common law to proceed upon indictments of felony, trespass, &c. and to order execution or reprieve; and they have power to discharge such prisoners as upon their trials shall be acquitted; also all such against whom on proclamation made, no evidence appears to indict; which *justices* of oyer and terminer, &c. may not do. 2 Hawk. 24, 25. But these *justices* have nothing to do with any person, nor in the custody of the prison, except in some special cases; as if some of the accomplices to a felony may be in such prison, and some of them out of it, the *justices* may receive an appeal against those who are out of the prison, as well as those who are in it; in which appeal after the trial of such prisoners, shall be removed into B. R. and process issue from them against the rest. But if those out of prison be omitted in the appeal, they can never be put into any other; because there can be but one appeal for one felony.

In this way the gaols are cleared, and all offenders tried, punished, or delivered, in every year.

Their commission is now turned over to the *JUSTICES of assize*.

JUSTICES of nisi prius, are now the same with *justices of assize*. It is a common adjournment of a cause in the common pleas, to put it off so such a day. *Nisi prius* *justitarius occurrat ad eos partes ad terminos assize*: from which clause of adjournment they are called *justices of nisi prius*, as well as *justitia of assize*, on account of the writ and actions they have to deal in. See *NISI prius*, and JURY.

JUSTICES of oyer and terminer, were *justices* deputed on some special occasions to hear and determine particular causes.

The commission of oyer and terminer is directed to certain persons, upon any insurrection, heinous demeanour, or trespass committed, who must first enquire, by means of the grand jury or inquest, before they are empowered to hear and determine by the help of the petit jury. It was formerly held, that no judge or other lawyer could sit in the commission of OYER and TERMINER, or in that of goal-delivery, within the county where he was born or inhabited; but it was thought proper by 12 Geo. II. cap. 27. to allow any man to be a *justice of oyer and terminer* and general goal-delivery, within any county of England.

JUSTICES of the peace are persons of interest and credit, appointed by the king's commission to keep the peace of the county where they live.

Of these, some, for special respect, are made of the quorum, so as no business of importance may be dis-

bites, and being in their verdict of the pannel found guilty or not guilty. If not guilty, the lord is called a lord of grace, they condemn, and order the sentence of condemnation to be pronounced against the criminal by the mouth of the doanor. It has been strenuously maintained by some, and as strenuously controverted by others, that an *ayia* lies from this court to the house of lords. The lord of grace likewise goes circuit twice a year, viz. in May and October, into the country, which is divided into three circuits, the north, west, and south, where *ayias* are held, and criminals tried, as mentioned above.

JUSTICES, in *Law*, a writ directed to the sheriff in some special cases, by virtue of which he may hold plea of debt in his county-court for a large sum; whereas otherwise, by his ordinary power, he is limited to sums under forty shillings.

JUSTIFIABLE *murder*. See *HOMICIDE*.

JUSTIFICATION, in *Law*, signifies a maintaining, or showing a defendant *reason* in court, why the defendant did what he is called to answer. Pleas in *justification* must be forth, some special matter; thus, on being first for a trespass, a person may justify by proving, that the land is his own freehold; that he entered a house in order to apprehend a felon; or by virtue of a warrant, to levy a forfeiture, or in order to take a distress; and in an *assault*, he may do it out of necessity.

JUSTIFICATION, or **JUSTIFYING**, *among Letter-Flourishers*. See *Letter-Flourish*.

Among Priests, it denotes the proper adjustment of the lines and pign.

JUSTIFICATION, in *Theology*, that act of grace which renders a man just in the sight of God, and worthy of eternal happiness.

The Romanists and Reformed are extremely divided about the doctrine of *justification*; the latter contends for *justification* by faith alone, and the former by works.

JUSTIFYING *law*, in *Law*. See *BAIL* *above*.

JUSTIFYING *reason*. See *GRACE*.

JUSTITIA, in *Law*. See *PLAT*.

JUSTNESS, the exactness or regularity of any thing.

Justness is chiefly used in speaking of thought, language, and sentiments. The *justness* of a thought consists in a certain precision or accuracy, by which every part of it is perfectly true, and pertinent to the subject.

Justness of language consists in using proper and well-chosen terms, in not saying either too much, or too little.

M. de Mere, who has written on *justness* of mind, distinguishes two kinds of *justness*; the one arising from taste and genius; the other, from good sense, or right reason. There are no certain rules to be laid down for the former, viz. to show the beauty and exactness in the turn, or choice of a thought; the latter consists in the just relation which things have to one another.

JUSTY, in *Architecture*, the *low* *platforms* standing on piers, near the docks and projecting without the wharves for the more convenient docking and undocking ships.

JUTRA, in *Botany*, a name used by some authors for the tree which fruit is the tamarind of the Indians.

JUVENILIA, or **JUVENILES** *ludæ*, games, exercises of body, and combat, instituted by Nero the first time he became emperor.

They were celebrated in private houses, and even the women had a share in them: probably they were the same with what were otherwise called *Nemora*.

JUVENIS, in *Metaphysics*, the goddess who presided over youth among the Romans. This goddess was long honoured in the Capitol, where Servius Tullius erected her statue. Near the chapel of Minerva there was the altar of *Juvenis*, and upon this altar a picture of Proserpine. The Greeks called the goddess of youth *Hæra*; but it has been generally supposed that this was not the same with the Roman *Juvenis*.

JVY, *brava*, in *Botany*, a genus of the *pentandria monogynia* class. Its characters are these: the flowers are cut into five parts, and the calyx is divided into five parts, and fits upon the perianth. The flower has five oblong petals, and five awl-shaped stamens; the anthers, which is situated below the flower, becomes a globular berry without cell, enclosing five large seeds, convex on one side, and angular on the other. There are two species.

While the stalks of the common *Jvya* either on the ground, upon walls or other supports, they seldom produce flowers; which has occasioned its being called sterile, or barren *Jvya*; but when the branches get above their support, or grow from it, they produce flowers at the end of every shoot: these appear in September, and are succeeded by berries, which turn black before they

are ripe: these are formed into round bunches, which are called *grapes*; and from these the epithet *variegata*, so frequently used by botanists, is taken.

Jvya is a very well known plant; and it is very certain, from all the writings of the ancients, that they, when they wrote with propriety, meant the same plant by the word *Jvya* that we do at this time. There is, however, in Pliny, a passage which has appeared unaccountable to his commentators, and which seemed to point out to some other plant than that of the ancients by the name *Jvya*, besides the *Jvya*. See *CISTUS*.

The leaves of *Jvya* are seldom used internally, but outwardly they are applied to ulcers, to keep them cool, and free from inflammation, as also to scabs, rashes, and scalds. Mr. Boyle, in his *Essays of Experimental Philosophy*, commends a large dose of the full ripe berries, as a remedy against the plague; and it is said, that in the London plague, the powder of them was given in vinegar, or white wine, with success; and they have been recommended in small doses, as a cathartic and sudorific. Schroeder says, they purge upward and downward. The gum of *Jvya* is somewhat caustic, and recommended to take away spots and freckles out of the face. This resinous juice, exuding from the stalks of *Jvya*, has been recommended as corroborant and resolvent, in catarrhes and uterine obstructions; but has been rarely used, except as an ingredient in plasters; nor does it appear to possess any virtues which common resin has not in an equal degree.

Jvya-resin is brought from Persia, and some other of the hot countries, where alone it is to be found in any considerable quantity. Mr. Ray, indeed, mentions some of it having been found in *ruari* in Worcestershire, and other authors in other parts of Europe; but these are only singular instances of what may happen, our shops being obliged to be supplied from the East.

The ancient Greeks were acquainted with this resin, which the Arabian called *gummi Jvya*, as some also do to this day. It is to be employed with discretion, and to make a ointment for scalds and burns, but is never used by us with these intentions. The Persians esteem it much as an astringent.

JVY *tree* in *Botany*. See *KALMIA*.

JVY, *grains*. See *GEORGE*.

JVY, *fish*. See *PETRIUS*.

JVY, *fruit*. See *MOORE*.

JUXTAPosition, is used by philosophers to denote that species of growth, which is performed by the apposition of new matter to the surface, or outside, of an old.

In which sense, it stands opposed to *intussusception*; where the growth of a body is performed by the insertion of a piece within it, diffused through it. See *NUTRITION*.

JXALOS, in *Botany*, a name given by the Greek writers to the plant, which we call the *chamois*.

Its characters are these: it has oblong, permanent stamens, or bracts, which include the perianth; and the flower has six petals, which are equal, and three awl-shaped stamens; it has an oval alter-scattered perianth, situated below the flower, with a single style; the perianth altered because an oval capsule with three cells, filled with roundish seeds. It has nine species, natives of the Cape of Good Hope, where the natives greatly esteem the roots a food. Miller.

JXIAS, in *Botany*, a name given to the chameleon thistle of the white kind; and in the materia medica of the ancients, to a poison, against which they have prescribed many remedies. See *CHAMÆLEON*.

JXOPUS, in *Botany, a name given by Corbin, and some other authors, to the chondrilla or succory. Ger. Emaci. Ind. 2.*

JXORA, in *Botany, the name of a genus of plants of the *tetrandria monogynia* class; the characters of which are, that the calyx is a small erect perianthium, divided into four segments, and remaining when the flower is fallen; the flower consists of one petal, which is a slender, cylindrical, and very long tube, with a flat border, divided into four segments, of an oval figure; the stamens are four very short and crooked filaments, placed in the notches of the flower; the anthers are oblong; the perianth of the pistil is roundish; the style is slender, and of the length of the tube; and the stigma is bifid; the fruit is a roundish berry, containing only one cell, in which are four seeds, convex on one side, and angular on the other.*

JYAR, in *Chronology*, the second month of the ecclesiastical Jewish year, answering to part of our April and May.

JYNX. See *WYNX*.

IZTICHULOILI, in *Natural History*, the American name of a stone found in New Spain, and some other places; it is very hard, of a beautiful black, and takes a fine

IZT

fine polish. The Americans are very fond of it as a gem, and wear it by way of ornaments. De Laet mentions an American stone in his possession, which was cut by the Indians into a flat oval plate, and was of a beautiful black, but with two round spots of a silvery white. He supposes this to have been the *aterius lapis*, and probably it was either that stone, or of the species here mentioned.

IZTICPASO-QUER/ALLI is a stone of which the name given by the natives is *IZTICPASO*. It is a stone famous for its virtue in curing the colic, and other diseases, externally applied. It is of a beautiful green colour, and is by Nicotius noted a con- siderable quantity of emerald, but is more precious, a very fine

IZT

lapis nephriticus, of a pale green colour, very hard, and more pellucid than the other species of that stone, but it always shewing that greasy look on being polished, which characterizes all the nephritic stones. It is usually found in large masses, and the Indians cut it into flat plates, which they apply to the navel in the colic, and in other diseases, to the part affected, and suppose it has great power in promoting a discharge of the noxious humors.

IZTICPASO, in *Natural History*, the American name of a species of stone, of which the natives made their weapons of war, &c. before they knew the use of iron. It is called by De Laet and other authors, *lapis NOVACULA- RIVUS*.
